THE COLD REGIONS RESEARCH AND ENGINEERING LABORATORY

In nearly half the land of the Northern Hemisphere, the cold of winter freezes the earth and covers it with ice and snow. Low temperatures continue throughout the year in much of the Arctic and Antarctic, perpetually challenging the men and women who live and work there.

To adapt to the environmental conditions of these cold regions, we must fully understand their special characteristics. We must determine how the cold affects our activities and how our civilization in turn affects the cold regions. We must also learn how to adjust to the extreme changes that take place between summer and winter seasons.

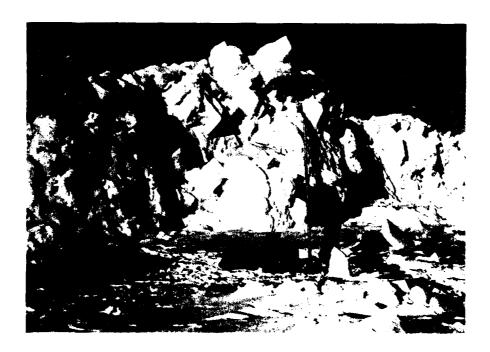

Gaining this knowledge through scientific and engineering research, and making the results available to governmental, military and other public organizations, is the job of CRREL—the Cold Regions Research and Engineering Laboratory of the U.S. Army Corps of Engineers.

THE MISSION

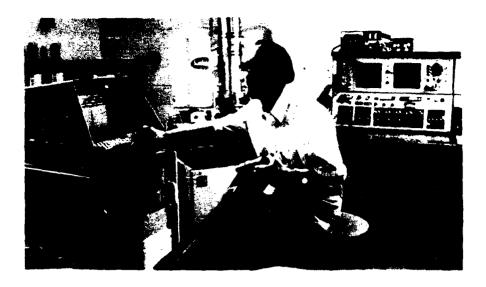

CRREL is a federal laboratory with a special mission—to understand the characteristics of the cold regions of the world and to apply this knowledge to make it easier for people to live and work there.

CRREL was created in 1961 by combining two existing Corps of Engineers organizations: the Arctic Construction and Frost Effects Laboratory and the Snow, Ice and Permafrost Research Establishment. Between them the two labs brought together at CRREL a group of research personnel with expertise in virtually all aspects of cold regions science and technology.

As a Corps of Engineers lab, CRREL has the advantage of the Corps' long-held tradition of service to the nation. CRREL research facilities and expertise are available to any federal, state or local agency that has need for them, and work has occasionally been done for private organizations as well. This approach helps to account for the diversity of research activities at CRREL and the overall character of the laboratory. Each research or study project, whether funded by the Corps of Engineers or other agencies, has a well-defined scope and objective chosen by its sponsor.

Sonar profiling of pressure ridge keel in Beaufort Sea.

CRREL PERSONNEL AND FACILITIES

Cold regions science and technology is a specialty that cuts across traditional disciplinary lines. As a result, the CRREL staff is quite diverse, with specialists from many different backgrounds. The total staff numbers about 300, including more than 100 research scientists and engineers. These researchers include civil, hydraulic, electrical, chemical and mechanical engineers, and agronomists, biologists, chemists, geographers, geologists, geophysicists, glaciologists, meteorologists, physicists and soil scientists. In addition, scientists and engineers from other institutions often pursue long-term research projects at the laboratory.

The support staff at CRREL also comprises a variety of professionals. Administrators, support engineers, technicians, computer specialists, photographers, illus-

Instrumentation in vehicle for measuring mobility through snow

Model of ice control structure in Ice Engineering Facility

trators, editors, typesetters, secretaries and dozens of others help to keep the laboratory running smoothly. These personnel often bring their expertise outside CRREL when needed for the research projects of other organizations.

The physical facilities that support the CRREL research effort really merit the description "unique." The main laboratory building contains 24 coldroom laboratories, many capable of achieving temperatures of -30 °C or below. Along with the cold laboratories are chemistry, physics, soils and electronics labs with highly specialized equipment for research at below-freezing temperatures.

In 1978 an Ice Engineering Facility was completed that is devoted to the study of problems caused by ice in waterways. This lab, acclaimed as the finest in the world, permits research that will lessen the effects of winter on the nation's waterways. In the Ice Engineering Facility is a refrigerated modeling area in which scaled-down rivers, harbors and lakes can be studied, a tilting refrigerated flume for river ice research, and a large test basin in which ice force problems can be studied at nearly full-scale dimensions.

The Frost Effects Research Facility, completed in 1985, is be devoted to the study of frost action in soils. This laboratory contains refrigerated research areas for below-freezing testing of pavements, foundations and underground utilities, and permits the study of destructive freeze-thaw cycles in a controlled setting.

CRREL also has an Alaskan Projects Office at Fairbanks with a research and supporting staff to aid in conducting CRREL's many projects in Alaska. In Fox, Alaska, CRREL excavated and helps to maintain a research tunnel in permafrost, the only facility of its type in the Western World.

CRREL RESEARCH

Snow and ice

Basic to the understanding of the cold regions is the study of snow and ice. Because they change with the characteristics of their environment, snow and ice are far more complex than most people realize.

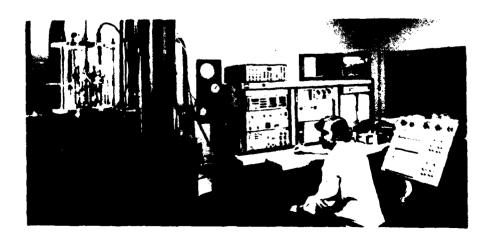

Drilling through ice in Antarctica

Examining an ice core

CRREL scientists and engineers have extensively studied both freshwater ice and sea ice. They have extracted drill cores from ice caps, icebergs and sea ice floes to scrutinize them with a number of analytical methods. Crystalline structure, which can greatly affect strength characteristics, has been investigated microscopically and with specialized radar devices. The minute quantities of certain elements in ice cores have been determined to the precision of 1 part per billion, and electron micrographs have revealed trace particles in snow crystals under thousands of powers of magnification.

The accumulation of ice on helicopter blades, ship superstructures, and communications antennas is a problem that has received considerable attention. CRREL researchers have explored the basic mechanisms that cause the ice accumulation and have developed methods for its prevention.

Ice can be a source of support for buildings, vehicles and machinery placed over water bodies or on glacial ice. But ice can also be a source of destruction when sheets of sea ice crush against navigation structures or river ice smashes against bridges. To

Strength testing machine

make use of its positive aspects and to guard against its destructive effects, the engineering properties of ice must be thoroughly known. Strength testing of ice samples and the measurement of ice forces on instrumented structures has revealed much information about the basic properties of different types of ice.

Snow also takes many different forms, depending on temperature, age, and snow-pack pressure. In glaciers, snow is transformed by the pressure of the accumulating snowpack first into a consolidated substance called firn and then eventually into ice. The massive ice sheets—such as those in Greenland and Antarctica—were formed in this way, and examination of the drill cores has revealed thousands of years of climatic history.

Research on mountain glaciers has helped to explain the forces that were working thousands of years ago when much of the Northern Hemisphere was covered with ice. The accumulation and breakup of the massive Antarctic glaciers have been carefully studied, as any fluctuation could drastically affect the global climate and the level of the world's oceans. Even the effects of the eruptions of Mt. St. Helens on its glaciers have been observed by CRREL scientists.

Melting of snow and the subsequent runoff are important to flood control and hydroelectric power production. Predictive models developed for estimating snowmelt and runoff have compared favorably with results from test sites. Eventually this work may result in accurate methods of predicting the amount and rate of spring runoff into watersheds throughout the country.

Frozen ground

Along with snow and ice, the other major natural material in cold regions is frozen ground. This material is even more complex, as it can take a multitude of forms. In the Far North, permanently frozen ground or permafrost is of particular concern because ice-rich permafrost will melt and settle if seriously disturbed. In virtually all areas with subfreezing temperatures, frost heaving can be a very destructive force to roads, airfields, pipelines, and all types of foundations.

An extensive effort has been made to understand the basic mechanisms of frost heaving so that this phenomenon can be reliably predicted. Although heaving can be

Installing a temperature-monitoring system in ground along trans-Alaska pipeline haul road

prevented by placement of soils that permit sufficient drainage, these soils are becoming increasingly scarce and expensive in many areas. Special techniques, such as surrounding problem soils with water-resistant membranes and precisely classifying soils with marginal frost susceptibility, promise to reduce both construction costs and potential for frost damage.

As with snow and ice, the mechanical properties of permafrost and seasonally frozen ground must be well understood before construction on these materials can take place. A number of laboratory and field tests have been devised to determine the moisture content and the frost-susceptibility of soils. In permafrost regions, an extensive program has sought to determine the ground ice content at substantial depths by electromagnetic methods and core drilling. CRREL researchers have helped to discover the characteristics of the permafrost beneath the Beaufort Sea near the oil fields at Prudhoe Bay, Alaska.

Cold regions construction

Among CRREL's first accomplishments was the design of airfields and living facilities in Greenland and Antarctica. This emphasis on cold regions construction has actively continued since that time. Major accomplishments have been the moving of a 3300-ton DEW Line station in Greenland onto a new and more stable foundation, and assistance in preparing design and installation procedures for the thousands of piles that support the aboveground portions of the trans-Alaska pipeline.

The design of roads and airfields has received particular emphasis. Experimental roads in New Hampshire and Alaska have tested new building techniques for cold regions. A study of the "haul road," built to bring materials to construction sites along the trans-Alaska pipeline, has shown the 360-mile-long road's response to the harsh northern climate and its effects upon the surrounding environment. In remote areas of Alaska, construction of airfields that are insulated from the permafrost has prevented disturbance of the ground ice and deterioration of the tundra.

Measuring movement of trans-Alaska pipeline

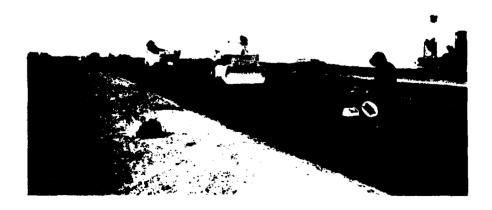

Air-transportable shelter

CRREL engineers have designed an air-transportable shelter for use in severe cold regions, and have conducted a long-term program on the correct design of roofs in heavy snowfall areas. From an extensive statistical analysis, a method of estimating roof snow loads for any area in the United States has been developed. In one application of their expertise, CRREL engineers determined the roof load at the time of the collapse of the huge roof of the Hartford, Connecticut, Civic Center.

Other CRREL construction-related research has investigated the use of special asphaltic paving mixtures and concretes that can be placed at low temperatures. Blasting techniques for use in permafrost and on ice have been developed. And CRREL engineers have worked with several agencies in remedying the detrimental effects of cold weather on existing facilities. In particular, one program found better ways to repair potholes in northern roads.

Land transportation

In areas where no roads exist or where they are clogged with snow, land transportation with conventional vehicles can be extremely difficult or virtually impossible. This problem has been addressed in two ways. First, methods are being developed for predicting the performance of wheeled and tracked vehicles in snow so that their design can be improved.

Laying asphalt concrete at Deadhorse Airfield, near Prudhoe Bay, Alaska

A second approach was a study of the use of surface-effect vehicles ("hovercraft") in arctic regions. These vehicles, modified for arctic use, were found to work well over snow-covered tundra, and they had little effect on the underlying permafrost.

Environmental protection

Due to the instability of ice-rich permafrost and the short growing season in northern regions, environmental protection is crucial. Several CRREL researchers have taken part in studies of the climate and biology of northern Alaska that are providing the first detailed documentation of this environment.

The impact of civilization has also been closely monitored. A long-term study has shown the effects of artificial oil spills on vegetation in a controlled environment, and the clean-up methods for spills along the trans-Alaska pipeline have been carefully observed to determine their effectiveness.

Restoration of areas damaged by construction activities has been documented and strategies developed to speed recovery. CRREL scientists have monitored erosion control and restoration activities along the entire trans-Alaska pipeline and on test slopes in New Hampshire and Alaska. Procedures for mapping wetlands through aerial photography and satellite imagery are being developed as part of a nationwide Corps of Engineers land use inventory. Similar remote sensing methods have assessed shore erosion in the Great Lakes and at Cape Cod and determined the potential environmental impact of construction projects in Alaska and northern Maine.

A multinillion dollar research program on improving methods for the land treatment of wastewater has been completed. Land treatment renovates municipal wastewater in a scientifically controlled manner to maximize the removal of waste substances and to minimize environmental effects and energy costs. The land treatment research program has placed this new technology on a firmer engineering basis so that millions of dollars will be saved in the construction and operation of new systems.

Sampling wastewater applied to a land treatment system

Blasting an ice jam.

High flow bubbler system (foreground) to keep ice from entering lock

Ice engineering

CRREL's Ice Engineering Facility has already been used in a variety of ways to improve winter navigation in cold regions. Studies of model icebreakers, conducted in the large refrigerated test basin, have resulted in devices that keep ice from damaging the ships' propellers. Studies of the interaction of moving ice sheets with test structures have helped to explain the destruction of offshore navigation facilities and to formulate new designs.

Refrigerated flume studies have resulted in methods for minimizing ice accumulation at dams and water intakes. Large-scale modeling of ice control structures in the Ice Engineering Facility's research area has demonstrated how existing structures can be modified and new ones designed to help protect shipping in ice-clogged northern rivers. As ice jams cause serious flooding each year in northern communities, the mechanics of ice jamming have received considerable attention so that this phenomenon can be prevented or controlled.

Various methods of keeping navigation locks free of ice have been devised to help extend the navigation season of the upper Ohio River system and St. Lawrence Seaway. The development of underwater air bubblers to keep navigation channels open has been applied extensively in northern harbors and navigation facilities.

Energy conservation

Due to the large heating requirements of buildings in cold regions, several projects have focused on conserving energy while maintaining comfortable living conditions. Infrared sensing devices have been used extensively to detect heat losses and wet in-

Checking heat flow data

sulation. From these infrared surveys, recommendations can be made as to how to most cost-effectively improve the thermal performance of a building's walls and roof.

Heat pumps for reclaiming waste heat from industrial cooling water have been studied and used to heat two buildings at CRREL. A method of analyzing the thermal losses from heat distribution systems has helped to maximize the efficiency of centralized heating systems, and a project in Alaska has assessed the use of waste heat for improving agricultural production in the Far North.

Military operations

To aid the Army in preparing for military action in cold regions is one of CRREL's continuing concerns. Field tests have shown that snow fortifications can be used for stopping small arms fire, and an extensive program has contributed to the design of a baseplate for a lightweight mortar.

Currently, CRREL is coordinating extensive tests on the effects of winter weather on the electro-optical guidance systems used in modern weapons. The test program will lead to an understanding of the performance of these systems during heavy snowfall and other adverse weather conditions. Another program is examining the effects of the cold regions environment on land mines.

Mine sensitivity test

CRREL library

TECHNICAL INFORMATION

Since scientific and technological research depends on the effective transfer of information, CRREL has a very active publication program. CRREL publishes approximately 100 technical reports each year, along with a general-interest newsletter. In addition, CRREL maintains a current international bibliography of available cold regions publications entitled the *Bibliography on Cold Regions Science and Technology*. Approximately 140,000 publications have been accessioned to date. New CRREL publications are listed in the laboratory's information bulletin and in a cumulative annual supplement. The results of many CRREL investigations are also published in professional journals.

The CRREL library maintains an extensive collection of material on cold regions science and technology. The library is open to the public and welcomes requests from other organizations for information about cold regions technical literature.

All CRREL publications can be obtained from the National Technical Information Service, Springfield, Virginia, 22161. Some are available directly from the CRREL Publications Office. For general information about the laboratory, contact CRREL's Public Affairs Office at the following address:

USACRREL
72 Lyme Road
Hanover New Har

Hanover, New Hampshire 03755

Telephone: 603-646-4292

(Autovon 684-4292)

CRREL welcomes requests from other organizations for assistance with cold regions problems. These requests will be forwarded to the engineer or scientist who specializes in the specific problem area.

DESCRIPTION OF CRREL TECHNICAL PUBLICATIONS

Bibliography on Cold Regions Science and Technology

The Bibliography on Cold Regions Science and Technology was first published in 1951 and is a continuing publication of the Cold Regions Bibliography Section of the Library of Congress. It is sponsored by and prepared for CRREL. Volumes 1-15 were issued as the Bibliography on Snow, Ice and Permafrost, SIPRE Report 12. Beginning with volume 16 the title was changed to Bibliography on Snow, Ice and Frozen Ground, with Abstracts, and with volume 23 the current title was adopted.

Nearly all of the literature cited in the Bibliography on Cold Regions Science and Technology has been placed on microfiche and is available from the Library of Congress or CRREL library. Those interested in purchasing a photocopy of documents cited should address their request to: The Library of Congress, Photo Duplication Service, Dept. C-177, 10 First Street S.E., Washington, D.C. 20540. A complete bibliographic citation should be given. Online search of the Bibliography on Cold Regions Science and Technology (File Cold) is offered by

ORBIT Search Service 8000 Westpark Drive McLean, VA 22102 703-442-0900 800-421-7229 FAX: 703-893-4632

Collect calls from Canada accepted.

You may contact the CRREL library for additional information.

Current Literature—Cold Regions Science and Technology

Current Literature is also prepared for CRREL by the Cold Regions Bibliography Section of the Library of Congress. All CRREL reports and outside publications are announced as published. The 12 monthly listings are proofed, cumulated and published along with indexes each year as the Bibliography on Cold Regions Science and Technology.

CRREL Reports

The results of all major research efforts at CRREL are published in the CRREL Report series.

Special Reports

The Special Report series contains a wide variety of types of reports that do not fall within the CRREL Report category, e.g. literature reviews, data compilations, interim reports.

Monographs

The Cold Regions Science and Engineering Monograph series comprises comprehensive reviews of a field of scientific or technical knowledge with analysis and evaluation.

Miscellaneous Publications

This series chiefly includes papers by CRREL authors that are published outside the laboratory (e.g. journal articles, conference papers, reports published by other agencies.)

Internal Reports and Technical Notes

The Internal Report series contains documents that have not been published for reasons such as excessive expense, limited interest, etc. Copies are available for review in the CRREL library. Technical Notes are informal, preliminary, unreviewed papers that are not intended for external distribution.

AVAILABILITY OF PUBLICATIONS

Most CRREL reports are announced as published in *Government Reports Announcements*, a semi-monthly abstract journal. They are available from the National Technical Information Service (NTIS), Springfield, VA 22161. The telephone number is 703-487-4650.

HOW TO ORDER

Three categories of order fulfillment are offered.

1. Rush Handling (replaces "Rush Order") is for customers who must have immediate delivery.

Rush Handling guarantees that a particular order will be filled within 24 hours of receipt. Rush Handling orders receive immediate validation, verification of availability, and individual hand processing through inventory control and the warehouse; priority printing if reproduction from film is required, and priority mailing.

Rush Handling orders for mailing rather than pickup are accepted only from customers having NTIS Deposit Accounts or American Express, Visa, or MasterCard Accounts.

Rush Handling orders may be placed only by telephone, telegram, Telex, Telecopier or customers in person; not by mail. Customers must use order numbers.

Rush Handling for delivery to customers by First Class Mail adds \$10 to the cost of each item or copy ordered.

Rush Handling for pickup in Springfield or D.C. adds \$7.50 to the cost of each item or copy ordered.

The Express/Rush phone number is 800-336-4700 or 703-487-4700.

2. Premium Service is a day and night toll-free telephone ordering procedure ensuring order processing and mailing within 4 to 9 days to NTIS Deposit Account or American Express, Visa or MasterCard customers. The \$3.50 fee for each item is waived if the order is not mailed within the specified period. Customers must use order numbers. Titles alone cannot be accepted in this procedure.

All Deposit Account, American Express, Visa, and MasterCard customers receive *Premium Service* identification numbers with which they may place telephone orders at any time. *Premium Service* benefits are toll-free calls with 24-hour availability, no busy signals, simplified ordering techniques (details with the identification number), postage savings and priority delivery.

Premium Service adds \$3.50 to the cost of each item ordered.

- 3. Regular Service will continue to operate with improved processing and stocking methods, optional priority mail delivery (\$3 North America; \$6 outside) and optional pickup in Springfield or D.C. Current parcel post deliveries using the U.S. Postal Service are completed within 9 to 30 days.
- 4. Online Ordering. The commercial vendors of the NTIS Bibliographic Data Base are experimenting with the convenience of online ordering of NTIS documents for their customers. Currently, online ordering is offered by the Systems Development Corporation (SDC). It permits SDC customers to charge their NTIS Deposit Accounts for orders that are transmitted daily to NTIS. Inquiries should be addressed to SDC, 2500 Colorado Avenue, Santa Monica, California 90406.
- 5. Telex. Ordering from NTIS may be speeded by the use of Telex. Customers may charge their Deposit Accounts, credit cards or ask for Ship & Bill Service. Ship & Bill Service costs \$5 extra for each order. The Telex number is 89-9405.
- 6. Orders for Foreign Destinations should be made through the sales agencies for NTIS products. Only if there is no sales agency in your country, should you order directly from NTIS.

For more information

For information not covered by the order form, please direct your inquiry to Customer Services, NTIS, 5285 Port Royal Road, Springfield, VA 22161; or Telephone (703) 487-4600 or (202) 724-3382.

HOW TO PAY

The prices in this catalog cover sales in the United States, Canada and Mexico. Buyers for foreign designations should request separate pricing.

The fastest service is provided to customers who charge against their NTIS Deposit Accounts or their American Express, Visa or MasterCard accounts, because the processing of such orders is simplest for NTIS. Holders of NTIS Deposit Accounts may replenish their accounts using the above credit cards. And new Deposit Accounts may be opened in the same manner.

Otherwise, payment by check or money order must accompany each order.

As an added convenience to customers who have established credit, a Ship and Bill Service is provided generally at a \$5 surcharge on each total order for documents, regardless of the number of documents ordered.

Retail Sales at Two Locations

NTIS has two retail sales locations in the Washington area.

In the District of Columbia, the NTIS Information Center and Bookstore is in the Pennsylvania Building, Suite 620, 425 13th Street N.W. Telephone (202) 377-0365. Several hundred best selling titles are displayed for sale and for immediate delivery without Rush Handling surcharge.

The Springfield Operations Center has a much more limited display of research reports, but any titles may be ordered for future delivery.

Prices for most reports are \$6.50 microfiche, \$9.95 Xerox copy.

How to Open a Deposit Account

Use the order form and send at least \$25, or enough to cover your first order, to NTIS Deposit Account, 5285 Port Royal Road, Springfield, VA 22161. Thereafter, keep at least \$25 on deposit or enough to cover two months' charges. Orders will not be processed for overdrawn accounts. You may deposit any amount prior to ordering. Some active customers keep several thousand dollars in their accounts to ensure the fastest possible service for large orders.

When your account is opened, you will receive preaddressed order forms to speed your shipments and simplify accounting and the recording of tax-deductible expenses.

NTIS FOREIGN REPRESENTATIVES

NTIS is represented in many countries around the world by local organizations. These representatives assure NTIS clients in those countries of fast and efficient service when transacting business with NTIS. They offer the convenience of accepting payment in local currencies and they can solve any order-related problem. These represen-

tatives also locate foreign technology for the NTIS collection.

NTIS customers in the countries listed should direct their orders and inquiries to the designated representatives.

NTIS foreign prices usually apply in countries other than the United States, Canada and Mexico. But, by special arrangement with the NTIS representatives in certain developing countries the North American price may apply. Customers ordering for destinations outside of the United States, Canada and Mexico may request the free current NTIS Foreign Price List (NTIS-PR-360-4), or ask for the specific foreign price of any product or service.

ARCTIC ENVIRONMENT AND THE ARCTIC SURFACE EFFECT VEHICLE. Sterrett, K.F., Jan. 1976, 28p., ADA-024 849, Bibliog-

raphy p.25-28. 31-4161

AIR CUSHION VEHICLES, SEA ICE, TOPO-GRAPHIC FEATURES, ARCTIC LANDSCAPES. GRAPHIC FEATURES, ARCTIC LANDSCAPES. This report summarizes the advances in understanding of the Arctic which have come about since the inception of the ARPA Arctic Surface Effect Vehicle Program in 1970, primarily as the result of CRREL's participation. Major efforts to increase knowledge of sea ice, terrestrial, and coastal topographic features are described. Special emphasis is placed upon the quantitative understanding of pressure ridging. Other areas of major interest are atmospheric characteristics and ecological effects. A list of publications generated is included.

PROTECTED MEMBRANE ROOPS IN COLD

Aamot, H.W.C., et al, Mar. 1976, 27p., ADA-025 226, 32 refs.

Schaefer, D. 31-4162

WATERPROOFING, INSULATION, ROOFS. COST ANALYSIS.

COST ANALYSIS.

Protected membrane roofs have the prerequisites for better performance and the experience to date is encouraging. The results of performance measurements of three roofs built by the Corps of Engineers verify that the mambrane remains at nearly constant temperature, independent of the weather, and that the insulation retains its integrity despite periodic wetting. Moisture absorption is slow and appears to stabilize in time due to the self-drying nature of the roof. Heat closes are increased due to rain, and extra insulation should be added to compensate for these losses. The resistance of protected membrane roofs to fire, traffic, impact, and other adverse forces is superior. So far, the initial cost of protected membrane roofs is at a premium, primarily due to the cost of concrete pavers. The initial cost premium can be justified, however, by the reduced repair and maintenance costs as indicated to date, and by the longer life expectancy of the protected membrane. The high probability of superior performance and cost effectiveness is a compelling reason to incorporate protected membrane roofs increasingly in Government construction. in Government construction.

CR 76-03

SURVEY OF DESIGN CRITERIA FOR HAR-BORS AND CHANNELS IN COLD REGIONS AN ANNOTATED BIBLIOGRAPHY.

Haynes, F.D., Mar. 1976, 32p., ADA-025 226. 31-4163

BIBLIOGRAPHIES, PORTS, CHANNELS (WA-TERWAYS), ICE LOADS, DESIGN CRITERIA.

A world-wide review of the literature applicable to the design of harbors and channels in cold regions was conducted. Forces due to ice movement present the dominant factor in the design of marine structures in cold regions. Expressions for calculating the ice force are presented. Other factors relating to design criteria such as construction materials, structure geometry, and methods of ice suppression are discussed.

ISLANDS OF GROUNDED SEA ICE.

Kovacs, A., et al, Apr. 1976, 24p., ADA-025 257, 26 refa.

Gow, A.J., Dehn, W.F.

31-4164

SEA ICE, ICE ISLANDS, SPACEBORNE PHO-TOGRAPHY.

TOGRAPHY.

Large areas of grounded sea ice have been reported by early arctic explorers and more recently by the U.S. Coast Guard. The ESSA, EPTS, NOAA and DMSP satellites now provide multispectral imagery with sufficiently high resolution to allow detailed sequential observations to be made of the movement and spatial extent of arctic sea ice. This report discusses the location, formation and decay of five large (> 30 aq km) islands of grounded sea ice in the southern Chukchi Sea as observed for an extended period of time using satellite imagery. Measurements of the bathymetry around one grounded sea ice feature are presented along with observations made and photos taken from the ice surface. The potential use of these sea ice islands as research stations is also discussed.

INTERPRETATION OF THE TENSILE STRENGTH OF ICE UNDER TRIAXIAL STRESSES.

Nevel, D.E., et al, Apr. 1976, 9p., ADA-027 042, 12

Havnes, F.D.

ICE STRENGTH, TENSILE STRENGTH, THEO-RIES, STRESSES

Griffith, and later Babel, have previously developed a tens fracture criterion for a two-dimensional state of stress. The Griffith, and later paper, have previously developed a temperature criterion for a two-dimensional state of stress. This theory is extended to the compression-compression region. From this theory the angle of fracture is developed. The theory is extended conceptually to three dimensions. al test data by Haynes for anow-ice are shown in this three-dimensional fracture theory. The test data are slightly less than those predicted when the void in the snow-ice is substricted.

WATER FLOW THROUGH VEINS IN ICE. Colbeck, S.C., Apr. 1976, 5p., ADA-026 631, 8 refs.

GLACIERS, WATER FLOW, WATER PRESSURE. POROUS MATERIALS.

POROUS MATERIALS.

Water flow through the vein structure of temperate ice is described as Darcian flow in which the pressure gradient is determined from vein size and overburden pressure. A solution method for the resulting equation is given and two special cases are considered. For steady flow the equilibrium vein size is a function of depth and, by neglecting the effects of diffusion, it is shown that flow perturbations introduced at the surface propagate downward at a constant speed. These perturbations propagate so slowly that even annual surface fluctuations of flow may be eliminated by diffusion before reaching the bottom of the glacier.

CANTILEVER BEAM TESTS ON REINFORCED

Ohstrom, E.G., et al, Apr. 1976, 12p., ADA-025 380, 6 refs.

DenHartog, S.L.

31-4167 ICE STRENGTH, ICE ROADS, PLOATING ICE. REINFORCEMENT (STRUCTURES).

REINFORCEMENT (STRUCTURES).

To determine the effectiveness of reinforcement in ice roads or other uses of a floating ice sheet a series of in-situ cantilever beam tests were run in both seawater ice and neahwater ice. Tests were run using 1-in-diameter tree branches, 3/16-in-diameter wire rope and 9/16-in-half-round wood dowels. The tests demonstrated clearly that properly placed reinforcement increases the bending strength of the ice and showed further that reinforcement reduces the chances of equipment loss. The question of whether to reinforce or simply grow a thicker ice sheet has not been addressed as this is more a problem of local economics.

PREDICTION OF UNFROZEN WATER CON-TENTS IN FROZEN SOILS FROM LIQUID DETERMINATIONS.

Tice, A.R., et al, Apr. 1976, 9p., ADA-026 632, 30

Anderson, D.M., Banin, A.

31-4168 SOIL WATER, UNFROZEN WATER CONTENT. 31-4168
SOIL WATER, UNFROZEN WATER CONTENT.
During the past decade a number of methods for measuring the amount of unfrozen water in partially frozen ground have emerged. Means of quickly and simply predicting unfrozen water contents in clay have become increasingly important with the growth of interest in encapsulating clay soils compacted at low water contents to serve as base courses for roads. Unfortunately the measurements require sophisticated equipment and, in most instances, specially trained operators. In an effort to simplify the task of obtaining water-ice phase composition data, methods of calculating phase composition curves from other, simpler measurements on soils have been acught. In this paper we present a method of deriving the measurement of unfrozen water contents at various temperatures from liquid limit determinations. Previous studies have indicated that phase composition curves can be well represented by a simple power equation, W sub u = alpha x theta sup beta, where W sub u is the unfrozen water content in g H20/g soil, theta is the temperature in degrees below freezing and alpha and beta are empirical constants characteristic of a given soil. When the liquid limits of a large group of soils encompassing a wide range of textures were regressed against values of alpha, the correlation was found to be remarkably good. This has permitted the development of a prediction equation of sufficient accuracy for general engineering use. CR 76-09

SITE ACCESS FOR A SUBARCTIC RESEARCH

Slaughter, C.W., Apr. 1976, 13p., ADA-026 624, 9 refa

31-4169

RESEARCH PROJECTS, REMOTE SENSING. SITE ACCESSIBILITY.

Access to study areas may be an important factor in long-term field-oriented research, particularly in regions without well-developed road and communications systems. In a well-developed road and communications systems. In a wildland hydrometeorology research project in subarctic Alaska, access to and within a 40-aquare-mile research watershed has been developed both in accordance with a general plan prepared at project inception and in response to developing research requirements. Foot trails, trails for "off-road" low-ground-pressure tracked vehicles, helicopter transport, long-term data recorders, and radio telemetry of data have all heen incorporated in an access and communications anates. all been incorporated in an access and communications system Cost estimates indicate that incorporation of gravel roads into the system would be economically advantageous, given adequate funding for initial road construction.

DE-ICING USING LASERS.

Lane, J.W., et al, Apr. 1976, 25p., ADA-026 637, 27 refa

Marshall, S.J.

31-4170 ICE REMOVAL, LASERS, STRUCTURES, DAM-AGE.

The feasibility of employing a laser to de-ice remote surfaces was investigated. A Nd:Glass laser, wavelength 1.06 micrometers, and a Ruby laser, wavelength 6943A, were used to irradiate ice grown upon six types of substrates - asphalt, brass, concrete, aluminum, steel, and stone. It was found that a single pulse, delivered to the interface between the ice and its abstrates a surface that the state of the a single pulse, delivered to the interface between the ice and its substrate at a power density of 100 million to 1 billion watts/cm2, produced fractures 0.1 to 2 cm in diameter for all substrates. If the initial fracture could be propagated by suitable scanning of the optical beam over the interface, the ice could be disrupted and thus removed from the substrate. The technique could also be a useful adjunct to de-icing methods that depend upon the existence of an initial crack. The process of producing the initial fracture was found to be limited by the thickness of the ice, the bubble content of the ice, and the focusing susten.

CR 76-11

EFFECTS OF RADIATION PENETRATION ON

SNOWMELT RUNOFF HYDROGRAPHS. Colbeck, S.C., Apr. 1976, 9p., ADA-025 763, 10 refs. For this report from another source see 31-4211. 31-4171

HYDROLOGY, RUNOFF, RADIATION ABSORPTION.

ABSORPTION.

Water flow through the unsaturated portion of a snowpack is calculated using various assumptions about radiation penetration into the snow. The results show that for the purposes of hydrologic forecasting, it is sufficiently accurate to assume that all of the radiation absorption occurs at the surface. The error in the calculation of flow is largest for very shallow snowpacks, but this error is reduced by radiation absorption at the base of the snow and by the routing of meltwater through the saturated basal layer.

HEAT TRANSFER CHARACTERISTICS OF MELTING AND REFREEZING A DRILL HOLE THROUGH AN ICE SHELF IN ANTARCTICA. Yen, Y.-C., et al, Apr. 1976, 15p., ADA-026 365, 3 refs.

Tien, C 31-4172

HEAT TRANSFER, BOREHOLES, ICE SHELVES, ICE MELTING, RÉGELATION.

The heat transfer processes associated with melting and refreezing a drill hole 500 m in depth and 0.150 m in initial radius through an ice shelf were approximately analyzed. The results were expressed in graphical form showing the time available for experimentation under the hole as a function of heating duration and heating strength. It was found that the refreezing of the drill hole had a much slower rate than the melting of the hole. (Auth.)

WINTER THERMAL STRUCTURE AND ICE CONDITIONS ON LAKE CHAMPLAIN, VER-MONT

Bates, R.E., June 1976, 22p., ADA-027 146, 9 refs.

LAKE ICE, THERMAL REGIME, ICE CONDI-TIONS, MEASURING INSTRUMENTS, UNITED STATES-VERMONT-LAKE CHAMPLAIN.

The thermal structure and ice conditions of Lake Champlain, a mid-latitude large lake, near Shelburne Point, Vermont, were studied during the winter of 1974-75. The lake was instrumented to a depth of 8.5 m with a string of highly calibrated thermistors, connected to a data logger highly calibrated thermistors, connected to a data logger on above which recorded water temperatures every four hours. An ice mooring system was developed to anchor the thermistor string so that ice and water temperatures could be obtained at known levels. This temperature recording system measured vertical and horizontal variations in ice and water temperature regimes during ice formation, growth and decay. Meteorological data were measured during the winter period November 1974 through March 1975 at the site. Ice stratigraphy was determined for the ice at the site at its maximum seasonal growth for comparison with ice from St. Albans Bay (at the northern end of Lake Champlain) which had formed earlier. Correlations were determined had between ice growth and accumulated degree days of freezing. The operation of a bubbler system installed near the measurement site around a service dock was observed.

CR 76-14 THERMAL POLLUTION STUDIES FRENCH CREEK, EIELSON AFB, ALASKA. McFadden, T., June 1976, 5p., ADA-027 405, 7 refs.

THERMAL POLLUTION, WATER POLLUTION,

IHEMMAL POLLUTION, WATER POLLUTION, UNITED STATES—ALASKA—EIELSON AFB. At the height of warm weather in Alaska in 1975, temperature measurements were made to determine the extent of the thermal impact on Prench Creek due to a condenser cooling water impact from the Bielson AFB Power plant. Water temperature measurements during a two-day period failed to show any significant thermal impact on the water in Prench Creek. It was concluded that no thermal pollution exists due to this warm water input at the volumes and conditions that presently exist.

REVEGETATION IN ARCTIC AND SUBARCTIC NORTH AMERICA—A LITERATURE REVIEW. Johnson, L.A., et al, June 1976, 32p., ADA-027 406, Bibliography p.22-28. Van Cleve, K. 31-4175

PLANTS (BOTANY), ARCTIC LANDSCAPES SUBARCTIC LANDSCAPES, REVEGETATION. ARCTIC LANDSCAPES. A literature review of revegetation and biological aspects of restoration research was completed for arctic and subarctic North America. Although there is a great deal of climatic variation in this region it is generally characterized by extreme conditions such as a short growing assess and permaferet. variation in this region it is generally characterized by extreme conditions, such as a short growing season and permafrost. Most of the revegetation research has been undertaken in the last six years as a result of increased natural resource development. The primary goal has been erosion control, with aesthetics, minimization of thermokarst, and production of browne as other objectives. Revegetation and long-term restoration methods depend upon such variables as the site conditions unvisent seems (sense-like variables). the site conditions, nutrient regime (especially se this is influenced by the climatic conditions in the Arctic and Subarctic), plant adaptations, and the selection of native or introduced species. Technologies which have been developed to meet these conditions primarily include seedbed preparation, use of seed mixes, and fertilization and seeding methods. Most of the research has focused on the use of agronomic grasses and legumes. These are selected on the basis of a number of factors, such as cold hardiness and growth form prior or evaluation in the laboratory and the field. The most successful species to date have been Arctared fescue and Nugget bluegrass in the Arctic, while these two as well as creeping red fescue, meadow foxtail, Frontier reed canarygrass, Durar hard fescue, slender wheatgrass, and Icelandic pos did well in the Subarctic. Similar methods have been attempted to a more limited extent with evaluation of native herbaceous and woody species which seem promising on the basis of natural succession studies. There are a number of continuing research needs for arctic and subarctic revegetation. These include fertilization strategies, development of specialized techniques (such as springing) for native species, and longer term studies. It is particularly important to integrate short-term revegetation methods with long-term restoration goals. the site conditions, nutrient regime (especially as this is influenced by the climatic conditions in the Arctic and Subarc-

MECHANICS OF CUTTING AND BORING. PART II: KINEMATICS OF AXIAL ROTATION MACHINES.

Mellor, M., June 1976, 45p., ADA-027 279, 11 refs. 31-4177

ROCK DRILLING, ROTARY DRILLING, AUGERS, TUNNELING (EXCAVATION), MECHANICAL PROPERTIES, EXCAVATION, CUT-TING TOOLS.

TING TOOLS.
This report, which is one of a series on the mechanics of cutting and boring in rock, deals with the kinematics of machines such as rotary drills, augers, tunnel boring machines, correr, and raise borers, in which the rotary cutting unit revolves about an axis that is parallel to the machine's direction of advance. The discussion and analysis covers the geometry and motion of various components of the cutting system, including such topics as tool trajectories, tool speeds, motions of the more complicated mechanisms, chipping depth, penetration rates, production and clearance of cuttings, tool angles, and spatial distribution of cutters. Worked examples are given to illustrate the application of various equations to practical problems.

CR 76-17
MECHANICS OF CUTTING AND BORING.
PART III: KINEMATICS OF CONTINUOUS BELT MACHINES.

ROCK DRILLING, EXCAVATION, CUITING TOOLS, CONTINUOUS BELT MACHINES.

TOOLS, CONTINUOUS BELT MACHINES. This report, which is one of a series on the mechanics of cutting and boring in rock, deals with the kinematics of machines which utilize a continuous belt as the cutting unit (e.g. coal saws, shale saws, digger-chain treachers). The discussion and analysis covers the geometry and motion of various components of the cutting system, including such topics as chipping depth, production and conveyance of cuttings, tool trajectories, tool speech, tool angles, and arrangement of cutting tools on the belt. Worked examples are included to illustrate the application of various equations to practical problems.

CR 76-18 THICKNESS AND ROUGHNESS VARIATIONS OF ARCTIC MULTIYEAR SEA ICE.

Ackley, S.F., et al, June 1976, 25p., ADA-028 086, 11 Hibler, W.D., III, Kugzruk, F.K., Kovacs, A., Weeks,

31-4179

SEA ICE, ICE COVER THICKNESS, SURFACE ROUGHNESS, MODELS.

Three surface elevation and ice thickness profiles obtained during the 1972 Arctic Ice Dynamics Joint Experiment Pilot Study on a multiyear ice floe were analyzed to obtain relationships between the surface elevation, thickness and physical properties of the ice. It was found that for ice freeboards Study on a multiyear ice floe were analyzed to obtain relationships between the surface elevation, thickness and physical properties of the ice. It was found that for ice freeboards from 0.10 m to 1.05 m shove sea level a linear relationship between the ice density and the freeboard could be postulated in a statistical relationship consistent with the observed physical properties, which indicate that as the ice freeboard increases, the ice salimity decreases and the higher freeboard or thicker ice therefore decreases in density. Using this variable density with freeboard relationship, a model was constructed to predict the ice thickness, given the ice freeboard and snow depth alone. The model was compared with two other models, one assuming constant ice density (independent of freeboard) and the other using smoothing filters for predicting the ice thickness. It was found that the variable density prediction model gave the best approximation to the observed ice thickness, with a standard error between the measured and predicted value of about 0.4 m, compared with errors from 50 to 100% higher for the other two models. The model was also compared with data on multiyear ice from two other investigations in different regions and was found to give error estimates similar to the error of the data set on which the model was based. It is therefore concluded that the model can be useful to estimate multiyear ice thicknesses from surface elevation information obtained either by ground-based techniques or by serial methods such as laser profilometry or stereo serial photogrammetry. The effect of the variable density on estimates of the stresses from sources other than isostatic imbalance loading was examined and the results are presented in an appendix. Consideration of this property led to the conclusion that stresses from sources other than isostatic imbalance must account for 75% or more of the bending stresses necessary to induce cracking in multi-year ice.

CR 76-19 WASTEWATER RENOVATION BY A PROTO-TYPE SLOW INFILTRATION LAND TREAT-MENT SYSTEM.

Iakandar, I.K., et al, June 1976, 44p., ADA-029 744, Bibliography p.33-35. Sletten, R.S., Leggett, D.C., Jenkins, T.F.

32-1066

WASTE TREATMENT, WATER TREATMENT. SOIL CHEMISTRY, SEEPAGE.

SOIL CHEMISTRY, SEEPAGE.

The feasibility of a slow-infiltration land treatment system as an alternative to advanced waste treatment of wastewater was studied using six outdoor test cells. Wastewater was applied to forage grasses by spray irrigation. Parameters studied were wastewater application rate, effect of pretreatment and soil type and seasonal effects on the treatment system. Activated sludge pretreatment of the applied wastewater did not improve the overall quality of the product water from this slow-infiltration system. The uptake of nutrients by forage grasses accounted for significant removal of nitrogen and phosphorus from applied wastewater during the growing season. Other renovative mechanisms, namely nitrification/dentrification of applied nitrogen and phosphorus immobilization and fination by the soils may have accounted for further renovation of the applied effluents. The nitrogen loading rate appeared to be the critical factor in limiting the amount of wastewater that could be successfully applied to this type of land treatment system, at least over the the amount of wastewater that could be successfully applied to this type of land treatment system, at least over the short term. Also the renovative mechanisms for nitrogen were found to be seasonally dependent. Due to decreased nitrification and sorption of ammonium by sold components nitrogen was stored in the winter months. The sorbed ammonium underwent nitrification in the warmer months, giving rise to a high concentration of nitrate. N in spring. The higher nitrate concentrations observed in leachast after the first twent of matternate continuations. the first year of wastewater application were attributed to mineralization of native organic-N. Application of 15 cm/week of secondary effluent containing 27 mg/l total

N to sandy loam soil produced percolate water containing NO3-N concentrations consistently in excess of accepted drinking water standards (10 mg NO3-N/l). Leaching phosphorus was not observed but needs further study to predict long-term effects. Winter-time application was successful in terms of operational parameters, but the renovative capacity for nitrogen was impaired. The effect on the cessum in terms or operational parameters, but the renovative capacity for nitrogen was impaired. The effect on the other water quality parameters such as suspended solids, BOD, fecal coliform and organic-C was essentially complete removal. There was a negative chloride balance which was presumed to be due to plant uptake.

APPARENT ANOMALY IN FREEZING OF OR-DINARY WATER.

Swinzow, G.K., June 1976, 23p., ADA-039 177, 9 refs. 32-1067

ICE FORMATION, ICE CRYSTAL NUCLEI, SUPERCOOLED WATER, IMPURITIES, TEMPER ATURE VARIATIONS, LABORATORY TECHNIQUES.

TECHNIQUES.

Under ordinary conditions the freezing of water begins with supercooling and ice nucleation, and proceeds at 0°C at the ice/water interface until ice formation stops. The presence of solutes, high pressure, or dispersal in fine proce causes the water to freeze at temperatures below 0°C (the so-called freezing point depression). Whenever freezing begins, it proceeds at a constant temperature at a temperature which becomes progressively lower. A temperature rise during ice formation is considered here to be an anomaly. Under all equal circumstances, the conditions under which an anomalous freezing temperature is observable appear to be very special. This report describes two different experiments displaying the anomalous rise of temperature after nucleation and during ice formation. In one case the water was dispersed in the fine pores of fine powders; in the other case pure water was frozen in a transparent insulated cell. Photographic observations were made; relations of ice surface to water volume were measured.

CR 76-21 COMPRESSIBILITY CHARACTERISTICS OF COMPACTED SNOW.

Abele, G., et al, June 1976, 47p., ADA-028 622, 5 refs. Gow. A.J.

32-1068 SNOW TEMPERATURE, SNOW DENSITY SNOW DEFORMATION, STRESSES, PHASE TRANSFORMATIONS, RECRYSTALLIZATION. TRANSFORMATIONS, RECRYSTALLIZATION. The effects of snow temperature and initial density on the stress vs density and stress vs denormation relationships were investigated for shallow compacted snow in the density range of 0.28 to 0.76 g/cu cm, for a stress range of 0.5 to 72 bars and a temperature range of -1 to -34C at a deformation rate of 40 cm/sec. A decrease in temperature increases the resistance to stress, the effect increasing with applied stress. For any stress, an increase in the initial density results in an increase in the resulting density, the effect decreasing with an increase in stress. The approximate yield envelopes, which define the stress required to initiate any deformation of snow of a particular density and temperature, were determined. Rapid compaction of snow results in extensive recrystallization, significantly different from that of naturally compacted snow. At a stress of 72 bars, transformation to ice occurs only at temperatures above -10C. -10C.

EVALUATION OF MESL MEMBRANE—PUNCTURE, STIFFNESS, TEMPERATURE, SOL-

Sayward, J.M., June 1976, 60p., ADA-027 834, 30 refs.

32-1069 SOIL STRUCTURE, SOIL STRENGTH, PROTEC-TIVE COATINGS, FROST PROTECTION, CEL-LULAR PLASTICS.

LULAR PLASTICS.
Several membrane materials used or considered for MESL (membrane-enveloped soil layer) utilization of poor soils in road construction have been tested for cold effect on puncture and stiffness. PE (polyethylene) film was also tested for solvent soak effects. A simple blunt needle apparatus was devised for puncture testing. For plastic films (mainly PE), both puncture resistance and stiffness increases at low temperature. For non-woven, spunbonded fabrica these properties are little affected by cold. For both non-wovens and PE film, puncture and bending strengths increase linearly with weight or thickness. The slope is steeper for the non-wovens, which generally are stronger on a per unit weight basis. PE film soaked in a hydrocarbon solvent swelled approximately 17% and lost about 30-40% of its puncture strength. These effects are apparently reversible upon drying. sweised approximately 17% and tost about 30-40% of puncture strength. These effects are apparently reversil upon drying. Consideration has been given to seals and patching requirements and to the drying of seals liquids when adhering film to film. Also considered has been possible slippage related to the reported low any of friction of plastic films in soil and the possibility lamination for improved membrane properties.

CR 76-23 STUDY OF PILES INSTALLED IN POLAR SNOW.

Kovaca, A., July 1976, 132p., ADA-029 191, 18 refs. 32-1070 PILE DRIVING, SNOW BEARING STRENGTH, SNOW MECHANICS, GREENLAND. VANADIUM AND OTHER ELEMENTS IN GREENLAND ICE CORES.

Langway, C.C., Jr., Weiss, H.V., Hurley, J.P., Kerr, R.,

SNOW COMPOSITION, CHEMICAL ANALYSIS, ICE CORES, ICE COMPOSITION, IMPURITIES, GREENLAND.

GREENLAND.

Chemical analysis of surface snows and deeper ice core samples from Milcent, Greenland, indicates a marine origin for Na and Cl and a terrestrial origin for Al, Mn and V. Pre-1900 enrichment factors, based on average crustal v. Pre-1901 enrichment factors, based on average crustal v. V. Pre-1900 enrichment factors, based on average crustal composition, are high for Zn and Hg and appear to be related to their volatility. A comparison of pre-1900 and 1971-1973 concentrations of V and Hg shows no decided increase from industrial production; however, the abundance of Zn (relative to Al) increased three-fold during this time period. The chemical composition of ancient ice is extremely useful in interpreting modern aerosols.

CR 76-25 BASELINE DATA ON THE OCEANOGRAPHY OF COOK INLET, ALASKA.

Gatto, L.W., July 1976, 84p., ADA-029 358, Bibliography p.78-81. 32-1072

OCEAN CURRENTS, TIDAL CURRENTS, WATER CHEMISTRY, SEDIMENT TRANS-PORT, TURBULENT FLOW.

WATER CHEMISTRY, SEDIMENT TRANS-PORT, TURBULENT FLOW.
The primary objective of this investigation was to compile baseline information pertaining to the ocean circulation, especially the extent and patterns of tidal currents and tidal funking, in Cook Inlet, Alaska, utilizing aircraft and satellite imagery with corroborative ground truth data. LANDSAT-1 and NOA-2 and -3 imagery provided repetitive, synoptic views of surface currents, water mass migration and sediment distribution during different seasons and tides. Color, color infarred and thermal infrared imagery acquired on 22 July 1972 with the NASA NP-3A aircraft were used to analyze currents, mixing patterns and sediment dispersion in selected areas. Temperature, salinity and suspended sediment concentration data and hand-held photography were utilized as ground truth information in the interpretation of the aircraft and satellite imagery. Coriolis effect, semidiumal tides and the Alaska current govern the estuary circulation. Clear, oceanic water enters the inlet on the southeast during flood tide, progresses northward along the east shore with minor lateral mixing, and remains a distinct water mass to the latitude of Kasliof-Niniichik. South of the forelands, mixing with turbid inlet water becomes extensive. Turbid water moves outh primarily along the north shore during ebb tide and a shear zone between the two water masses forms in mid-inlet south of Kalgin Island. Currents adjacent to and north of the forelands are complicated by tidal action, coastal configuration and bottom effects. Turbulence is greatest throughout the water column along the south shore and stratification is more pronounced in Kamishak and Kachemak Baya, especially when fresh water runoff is high. Most of the sediment discharged into the inlet is deposited on the extensive tidal flats or removed by tidal currents along the west side during ebb flow. Bottom scouring is evident along the east shore south of Pt. Possession. CR 76-26

DEBRIS OF THE CHENA RIVER.

McFadden, T., et al, July 1976, 14p., ADA-029 357,

Stallion, M. 32-1073

RIVERS, LOGIAMS, UNITED STATES—ALAS-KA—CHENA RIVER.

Debris over a 44-mile stretch of the Chena River was studied. The study area extended from the first bridge on the Chena Hot Springs Road to the Chena River Flood Control damsite. The purpose of the study was to assess the potential danger to the Chena River Flood Control Dam outlet structure. Debris was catalogued, log jams were measured, and sources of debris were studied. The average size of logs was determined, as well as the number of logs present on the river. The authors concluded that a serious debris problem existed and would remain serious for the foreseeable future. Recommendations for debris handling were made. Debris over a 44-mile stretch of the Chena River was studied.

CR 76-27
ENERGY BALANCE AND RUNOFF FROM A SU-BARCTIC SNOWPACK.

Price, A.G., et al. August 1976, 29p., ADA-030 096, Bibliography p.28-29. Dunne, T., Coibeck, S.C.

32-1074

SNOW HYDROLOGY, SNOWMELT, RUNOFF, MOISTURE TRANSPER, TUNDRA VEGETA-TION, FOREST LAND.

MOISTURE TRANSPER, TUNDRA VEGETATION, FOREST LAND.

In Part I a physically based model was used to predict
daily snowmelt on 2,000 ag m piots in the Suberretic. The
plots had a range of sepects and inclinations in boreal forest
and on the tundra. The energy balance, computed for
each of the plots, was compensated for differences in radiative
and turbulent energy fluxes caused by varied slope geometry
and vegetative cover. The turbulent energy fluxes were
also corrected for the effects of the stable stratification of
the air over the snow surface. The predictions of the
model were compared with daily melts derived from runoff
measured on the snowmelt plots. The results show that
the method is a good predictor of daily amounts of snowmelt,
although some uncertainties are introduced by changes in
the snow surface during the melt period. In Part II,
a physically based model of the movement of water through
snowpacks was used to calculate hydrographs generated by
diurnal waves of snowmelt on the tundra and in the boreal
forest of subarctic Labrador. The model was tested against
measured hydrographs from hillside plots that sampled a
range of aspect, gradient, length, vegetative cover, and snow
depth and density. The model yielded good results, particularly in the prediction of peak runoff rates, though there
was a slight overestimate of the lag time. A comparison
of predictions against field measurements indicated that, given
the ranges over which each of the controls is likely to
arry, the two most critical factors controlling the production for the controls is they to of predictions against field measurements indicated that, given the ranges over which each of the controls is likely to vary, the two most critical factors controlling the hydrograph are the snow depth and the melt rate, which must be predicted precisely for short intervals of time. Permeability of the snowpack is another important control, but it can be estimated closely from published values.

ANALYSIS OF EXPLOSIVELY GENERATED GROUND MOTIONS USING POURIER TECH-

Blouin, S.E., et al, August 1976, 86p., ADA-030 060, 18 refs.

Wolfe, S.H. 32-1075

SEISMIC SURVEYS, WAVE PROPAGATION, VI-BRATION, EXPLOSION EFFECTS, NUCLEAR EXPLOSIONS, EARTH MOVEMENT, FOURIER TRANSFORMS OF SELECTED GROUND-MO-TION TIME HISTORIES FROM FIVE UNDER-GROUND HIGH-EXPLOSIVE AND NUCLEAR DETONATIONS ARE USED TO DEFINE THE TRANSMISSION PROPERTIES (TRANSFER FUNCTIONS) OF THREE ROCK TYPES.

FUNCTIONS) OF THREE ROCK TYPES.

Absorption, a measure of a rock's energy dissipating characteristics, is expressed for each of the tests as a function of the frequency of transmission. Dispersion results from a variation in transmission velocity with frequency and is described for each test by a phase velocity spectrum. The ransmission properties from one of the sites are used to predict a ground-motion time history at that site from another nuclear event. The potential use of Fourier techniques to make ground-motion predictions and to measure in-situ material properties is discussed.

REMOTE SENSING, AERIAL SURVEYS, SPACE-BORNE PHOTOGRAPHY, INFRARED PHO-TOGRAPHY, LAND DEVELOPMENT, UNITED STATES—WISCONSIN.

The fe of this investigation was to assess the utility of rem sensing techniques in the study of lend users area. It following types of serial imagery were evaluated for this purpose: high altitude (60,000 ft) color, color infrared, multispectral black and white, and thermal; low altitude (less than 5,000 ft) color infrared, multispectral black and white, thermal, and passive microwave. A non-imaging hand-held four-band radiometer was evaluated for utility in providing data on suspended sediment concentrations. Land use analysis includes the development of manning and orasnité. of this investigation was to assess the The fe providing data on suspended sediment concentrations. Land use analysis includes the development of mapping and quantification methods to obtain baseline data for comparison to water quality variables. Suspended sediment loads in streams, determined from water samples, were related to land use differences and soil types in three major watersheds. A multiple correlation coefficient R of 0.85 was obtained for the relationship between the 0.6-0.7 micron incident and reflected radiation data from the hand-hald radiometer and concurrent ground measurements of suspended solids in streams. Applications of the methods and baseline data developed in this investigation include mapping and quantification of land use, input to watershed ranoff models. data developed in this investigation include mapping as quantification of land use, input to watershed runoff mode estimation of effects of land use changes on stream sediment tion, and remote sensing of suspended sediment conte of streams. High altitude color infrared imagery was four to be the most acceptable remote sensing technique if the mapping and measurement of land use types.

ANALYSIS OF POTENTIAL ICE JAM SITES ON THE CONNECTICUT RIVER AT WINDSOR,

VERMONT. Calkina, D.J., et al, Sep. 1976, 31p., ADA-031 572. 11

Hutton, M.S., Mariar, T.L.

32-1079 RIVER ICE, ICE JAMS, ICE MECHANICS, WATER FLOW.

WATER FLOW.

Sections in the Connecticut River where ice jam potential is high were identified through the use of low-altitude black and white photographs taken during low-flow, ice-free conditions. The hydraulics and mechanics of ice jam initiation were investigated in the river reach where these sections were identified. Cartain areas were found in the river that had a high susceptibility to ice clogging, but this high potential decreased with increasing discharge because of the improved surface conveyance of the ice through the reach. The stability of ice floss was established along the channel, but the flow generally became unstable as the flow increasion. This was calculated by using a Proude number criterion. Grounding locations for ice became evident when the critical Proude number was zero for a given thickness and water Grounding locations for ice became evident when the critical Froude number was zero for a given thickness and water depth. No single factor was determined to be responsible for initiating the ice jams in the Connecticut River at Windsor. Apparently there existed a multitude of interacting conditions: surface constrictions, possible high backwater conditions from the Brattleboro Dam, a solid ice cover in the backwater of the Brattleboro Dam that prevented ice transport from the Windsor area, deep pools followed by shallow depth sections upstream of bridge piers, a greater ice thickness accumulation of fragmented floes than would result if a uniform cover could be established in the same reach, and the diurnal fluctuation of river stage caused by the release of water at Wilder Dam.

CR 76-32 GROUNDED ICE IN THE PAST ICE ZONE ALONG THE BEAUPORT SEA COAST OF ALAS-

Kovacs, A., Sep. 1976, 21p., ADA-031 352, 13 refs. SEA ICE, FAST ICE, ICE PHYSICS, PRESSURE

RIDGES.

Four large grounded multi-year shear ridge formations were found in the grounded ice subzone of the fast ice zone near the Harrison Bay/Prudhoe Bay area of Alaska. A 166m-long cross section of one of these formations was obtained by leveling and sonar measurements. These measurements revealed that the maximum ridge height was 12.6 m and that the formation was grounded in 17-18 m of water. The salinity temperature, brine volume and density m and that the formation was grounded in 17-18 m of water. The salinity, temperature, brine volume and density of the ice were determined on aemples obtained by coring. The physical characteristics of the formations as observed in satellite, SLAR and aerial imagery indicate that these formations have not moved between the time of their formation in the fall of 1974 and August of 1976. Evidence of significant aeolian debris discoloring the ice is discussed. CR 76-33

BUILDINGS, HEAT LOSS, INFRARED EQUIP-MENT.

MENT.
During the winter of 1973-74 a mobile infrared thermography system was used to survey campus buildings at Dartmouth College, Hanover, New Hampshire. This report provides both qualitative and quantitative data regarding heat flow through a small area of a wall of one brick dormitory building before and after installation of aluminum reflectors between radiators and the wall. These data were used to estimate annual cost savings for 22 buildings of similar construction having aluminum reflectors installed behind 1,100 radiators. The data were then compared with the actual savings which were calculated from condensate meter data. The discrepancy between estimated and actual annual cost savings is explained in detail along with all assumptions required for these calculations.

CR 76-34 SOME CHARACTERISTICS OF GROUNDED PLOEBERGS NEAR PRUDHOE BAY, ALASKA. Kovacs, A., et al, Sep. 1976, 10p., ADA-031 844, 11 refs. For another version of this report see 32-1082. Gow, AJ. 32-1083

RHEOLOGICAL IMPLICATIONS OF THE INTERNAL STRUCTURE AND CRYSTAL FABRICS OF THE WEST ANTARCTIC ICE SHEET AS REVEALED BY DEEP CORE DRILLING AT BYRD STATION.

Gow, A.J., et al, Sep. 1976, 25p., ADA-031 745, Bibliography p.22-25. Williamson. T.

mson, T. 32-1097

ICE SHEETS, DRILL CORE ANALYSIS, ICE ME-CHANICS, ICE STRUCTURE, ANISOTROPY, ANTARCTICA—BYRD STATION.

Crystalline textures and fabrics of ice cores from the 2,164-m-thick ice sheet at Byrd Station, Antarctica, reveal the existence of an anisotropic ice sheet. A gradual but persistent increase in the c-axis preferred orientation of the ice methick ice sheet at Byrd Station, Antarctica, reveal the existence of an anisotropic ice sheet.

A gradual but persistent increase in the c-axis preferred orientation of the ice crystals was observed between the surface and 1,200 m. This progressive growth of an oriented crystal fabric is accompanied by a 20-fold increase in crystal size between 50 and 600 m, followed by virtually no change in crystal size between 600 and 1,200 m. A broad vertical clustering of c-axes develops by 1,200 m. Between 1,200 and 1,300 m the structure transforms into a fine-grained mossic of crystals with their basal glide planes now oriented substantially within the horizontal. This highly oriented fine-grained structure, which persists to 1,800 m, is compatible only with a strong horizontal shear deformation in this part of the ice sheet. Rapid transformation from single- to multiple-maximum fabrics occurs below 1,800 m. This transformation, accompanied by the growth of very large crystals, is attributed to the overriding effect of relatively high temperatures in the bottom layers of old ice at Byrd Station rather than to a significant decrease in stress. The zone of single-maximum fabrics between 1,200 and 1,800 m also contains numerous layers of volcanic dust. Fabrics of the very fine-grained ice associated with these dust bands indicate the bands are actively associated with these dust bands indicate the bands are actively associated with these dust bands indicate that plastic deformation (intracrystalline glide) in the zone of strong single-maximum fabrics, and movement of ice along discrete shear planes situated well above bedrock, are sho major contributors to the flow of the ice sheet. Any extensive shearing at depth could seriously distort stratigraphic records contained in the ice cores, such as climatic history inferred from stable isotope analysis. Also, the common practice of using simplified flow models to approximate the depth-age relationships of deep ice sheet coves may meed to be revised in light of the deformation

ROCK, FROZEN SOIL AND ICE BREAKAGE BY HIGH-FREQUENCY ELECTROMAGNETIC RADIATION. A REVIEW.

Hoekstra, P., Oct. 1976, 17p., ADA-039 178, 17 refs. 32-1098

ROCK EXCAVATION, FROZEN GROUND STRENGTH, EXCAVATION, DIELECTRIC PROPERTIES, ELECTROMAGNETIC PROPER-TIES, MATHEMATICAL MODELS.

TIES, MATHEMATICAL MODELS.

In the past decade, various workers have investigated the use of high-frequency electromagnetic radiation for breaking and excavating rock and frozen ground.

This report reviews the high-frequency dielectric properties of these materials, the physics of heating, and the existing literature on these subjects. The high-frequency dielectric properties of rocks and soils, and the absorption of energy by these materials, are mainly determined by their liquid water contents. Computer modeling was used to calculate absorption energy as a function of distance behind irradiated faces of earth materials. The resulting computations showed that most enery is absorbed in the first few continueters of frozen ground and weak soils. However, in hard rocks of low water content, electromagnetic waves penetrate more deeply, and significant amounts sous. However, in hard rocks of low water content, electromagnetic waves penetrate more deeply, and significant amounts of energy are also absorbed tens of centimeters behind the irradiated floes.

Test results showed that electromagnetic rock breakage is fessible only for excavations in hard rock; test results from the use of electromagnetic radiation for excavating tunnels in weak rocks and frozen ground are not pro

AIRBORNE RESISTIVITY AND MAGNETOME-TER SURVEY IN NORTHERN MAINE FOR OB-TAINING INFORMATION ON BEDROCK GEOLOGY.

Arcone, S.A., Delaney, A.J. 32-1099

MAGNETIC MEASUREMENT, BLECTRICAL RESISTIVITY, GEOPHYSICAL SURVEYS, GEOLOGY, UNITED STATES—MAINE.

GEOLOGY, UNITED STATES—MAINE.

Geophysical studies were conducted during September and October of 1975 in northern Maine to locate rock types suitable for construction purposes for the proposed Dickey-Lincolo School Dam Project. Simultaneous airborne magnetic meter and VLF electrical resistivity and of total magnetic intensity above the earth's background magnetic field. During the same time period, ground and multi-elevation surveys were performed over a special test sector of known geology. The ground and airborne study in the test sector aided in interpretation of the data by revealing a strong correlation between igneous geology, resistivity, and magnetic intensity. Lack of a similar correlation between resistivity and magnetic data in the remainder of the survey area suggested an absence of additional areas of igneous rocks. The multi-elevation survey of the test area indicated that changes in flight altitude, necessitated by the topographic relief encountered, would survey of the test area indicated that changes in might attitude, mocessitated by the topographic relief encountered, would not seriously affect the regional resistivity patterns. Although there was no strong evidence of igneous rocks outside the test sector, suitable rock types may exist within the Des geologic unit (cyclically bedded gray slate and sandstone) in the central part of the main survey area, where most of the high resistivity contours occur.

WATER ABSORPTION OF INSULATION IN PROTECTED MEMBRANE ROOFING SYS-

Schaefer, D., Oct. 1976, 15p., ADA-032 089, 12 refs. 32-1100

INSULATION. **PROTECTIVE** WATERPROOFING, ABSORPTION, ROOPS.

Current methods for evaluation of the moisture absorption of plastic insulations (ASTM-C-272-53 and ASTM-C-355of plastic insulations (ASTM-C-272-53 and ASTM-C-355-64) due to vapor pressure gradients or immersion rely on abort time periods to predict long term performance. This procedure may not provide accurate information on performance since in practice insulations may absorb more moisture than these tests indicate. A series of tests was conducted on extruded polystyrene roof insulation that had been in place, exposed to environmental moisture and pressure gradients, for a maximum of 36 months. Results indicate that moisture absorption of 1.5% by volume can be expected in the field.

CR 76-39 EFFECTS OF WASTEWATER APPLICATION ON THE GROWTH AND CHEMICAL COMPOSITION OF FORAGES.

Palazzo, A.J., Oct. 1976, 8p., ADA-032 774, 9 refs.

32-1101
WASTES, WATER, SOIL CHEMISTRY, WATER
CHEMISTRY, PLANTS (BOTANY), GRASSES.
The contribution of a forage mixture in the renovation of
wastewater by a prototype slow infiltration land treatment
system was studied from June 1974 to June 1975. The
forage was grown in six outdoor cells, three containing a
Windsor sandy loam soil and three a Cariton silt loam.
Three cells received primary and three received secondary
wastewater at various application rates. Crop yields, soils
and tissue analyses, plant removal efficiency and total uptake
of applied. Dry matter production, plant heavy metal concen-

trations, and plant removal of nitrogen and phosphorus all increased as the rate of applied wastewater increased from 5 to 15 cm/week. Total dry matter production ranged from 9.63 to 12.99 metric total/ha, and total uptake of nitrogen and phosphorus ranged from 309 to 453 kg/ha and from 32 to 42 kg/ha, respectively. An increase in wastewater application rates suppressed nitrogen and phosphorus removal efficiency by plants. Forages receiving 5 cm/wk of wastewater removed 474% and 83% of the N applied during the growing season, in contrast to the 44% removed by those treated with 15 cm/wk of wastewater. Forages grown on the Chariton soils produced a greater amount of dry matter and removed more N and less heavy metals than those grown on the Windsor soils. Soil analyses in spring 1975 showed reductions in soil pH and in the total amounts of exchangeable cations, as compared to analyses performed in spring 1974. Soils receiving the greatest application rate of wastewater showed the greatest reduction. total amounts of exchangeable cations, as compared to analyses performed in spring 1974. Solls receiving the greatest application rate of wastewater showed the greatest reduction. Wastewater application during 1974 increased the amount of soluble soil P. Higher amounts of soil-extractable P were also noted at the highest wastewater application rate.

PHOTOMACROGRAPHY OF ARTIFACTS IN TRANSPARENT MATERIALS. Marshall, S.J., Nov. 1976, 31p., ADA-033 670, 31 refa.

32-1102

ICE, IMPURITIES, PHOTOMACROGRAPHS.

Several original methods were developed to photograph artifacts in transparent materials such as ice. The artifacts, occurring in the surface, bulk, and interface, were generally, 0.01 mm to 70 mm in size. Sample preparation, illumination, focusing and other technical problems are discussed in detail. Several sample photographs are included.

CR 76-41 GEODETIC POSITIONS OF BOREHOLE SITES OF THE GREENLAND ICE SHEET PROGRAM. , S.J., Nov. 1976, 7p., ADA-033 840, 9 refs. 32-1103

GEODETIC SURVEYS. BORBHOLES, ICE SHEETS, ICE CREEP, GREENLAND.

SHEETS, ICE CREEP, GREENLAND.

Eight Geoceiver stations were established and suitably marked along or near the crestiline of the Greenland ice sheet during GISP field operations from 1971 to 1975. At one of these stations, DYE-3, repeated Geoceiver positions indicate an ice velocity of 12.7 m/yr on an azimuth of approximately 60 deg. Data from the International Greenland Glaciological Expedition (EGIG) surveys show that ice flow in the vicinity of Crete is redisting outward from a dome to the south. Two independent calculations of the state of equilibrium at Crete indicate ice sheet thinning rates of 0.25 to 0.37 m/yr, while direct measurement of elevation change by EGIG indicates nice sheet thickening rate of of approx 0.06 m/yr. Resolution of these differences must await turther geophysical work and deep drilling in the ice sheet.

CR 76-42 ARCHING OF MODEL ICE FLORS: EFFECT OF MIXTURE VARIATION ON TWO BLOCK SIZES.

Calkins, D.J., et al, Nov. 1976, 11p., ADA-033 841, 5

Ashton, G.D. 32-1104

EXPERIMENTAL DATA, FLOATING ICE, ICE

A study of arching of mixed, square fragmented ice floes at an opening in an ice boom is documented, using results from a model study in which two sizes of plastic blocks represented real ice. A power function, relating the upstream ice concentration to the ratio of a characteristic block dimenrepresented real ice. A power function, relating the upstream ice concentration to the ratio of a characteristic block dimension to the gap opening, is found adequate to distinguish between arching and nonarching events for block mixtures of two component sizes. It is demonstrated that when the respective total areas of the two block components are nearly equal, a minimum ice concentration initiates an arch across the opening. As the mixture of two sizes of blocks approaches a uniform (non-sized) mixture in higher concentration. across the opening. As the mixture of two sizes of blocks approaches a uniform (one-sized) mixture, a higher concentration of ice is needed to initiate the arch. When the ratio of the block dimension to the gap opening is equal to or less than 0.10, arching of the fragmented ice is not possible, even when the upstream ice discharge exceeds the maximum discharge of ice through a gap opening. The distribution of fragmented ice areas is an important parameter in establishing the minimum size of opening at which an ice boom will retain its arching capability.

SUPPRESSION OF ICE FOG FROM COOLING

McFadden, T., Nov. 1976, 78p., ADA-035 322, Bibliography p.71-75. 32-1105

ICE FOG, FOG FORMATION, FOG DISPERSAL, PONDS, ICE COVER EFFECT, PROTECTIVE COATINGS.

Ice fog generated at the Eielson AFB power plant cooling pond contributes heavily to the total ice fog problem on the base. Several methods for ice fog suppression were studied and two techniques were tested experimentally. periments were also conducted to determine the may of the various modes of heat transfer within the microchimate. Values of evaporative and radiative loss during ice fog are presented. Ice cover is Ice cover is sh

to be an effective ice fog suppression technique. Idonomolecular films are also shown to be effective and offer some unique advantages, such as ease of application and low overall cost. The hest normally lost to evaporation must be dissipated by other means during suppression. With the ice cover. During suppression with monomolecular films, the hest must be dissipated by increasing radiative and convective fores. The simplicity of application of monomolecular films, along with their lower cost, combine to make this technique attractive; however, the lower pond temperatures and increased suppression effectiveness weigh heavily in flavor of the ice cover technique.

CR 76-44 THERMODYNAMIC DEFORMATION OF WET SNOW.

Colbeck, S.C., Nov. 1976, 9p., ADA-033 830, 10 refs. 32-1106 WET SNOW, SNOW DEFORMATION, THER-

MODYNAMIC PROPERTIES. MODYNAMIC PROPERTIES.

The deformation of wet snow is explained in terms of the thermodynamics of the three phases of water. When deformation by particle rearrangement is fully developed, deformation can occur most rapidly by melting at the particle content. The rate of deformation is highly sensitive to the liquid water content, ionic impurity content, particle content area, and stress level. A model of the hydrostatic deformation of wet snow is constructed, and examples of the deformation of wet snow is constructed, and examples of the deformation.

of wet show is constructed, and examples of the deformation of wet snow are given for a variety of conditions. These results are in agreement with existing experimental evidence. The model socurately simulates the transient nature of the deformation and the effect of water content on the quasi-stable density of wet snow subjected to a constant stress.

AIR CUSHION VEHICLE GROUND CONTACT DIRECTIONAL CONTROL DEVICES. Abele, G., et al, Dec. 1976, 15p., ADA-034 825, 3 reft. Liston, R.A.

32-1107

AIR CUSHION VEHICLES, YAW.

AIR CUSHION VEHICLES, YAW.

The maneuverability of air cushion vehicles can become a serious operational problem when the vehicle's travel route is restricted by obtacles, alopes or cross-wind conditions, or when close-quarter turns are required. While improvement and perfection of serodynamic methods may be a more destrable approach, there is a practical limit to these methods, and the use of ground contact devices requires considerations for providing more positive directional control. Wheels deserve special attention, and therefore are analyzed in more detail because of their obvious application on a variety of land terrains. Brake rods and harrows are more suitable on water, ice and snow. The saucer-shaped ground contact device would cause the least ecological impact on fragile organic terrains such as tundra. Relative directional stability is evaluated in terms of the total yawing momentary produced by wheel arrangements (single, dual, tandem), location on the vehicle, and operational modes (free-rolling, braked, or a combination of the two). The available moments are plotted against the yaw angle of the vehicle to determine the most effective operational mode with a particular wheel arrangement for any yaw condition. The analysis is limited to retractable devices which act as moment producing brakes or rollers and do not serve as either propulsion or load support sids. Controlled ground contact with akirt sections to retractable devices which act as moment producing brakes or rollers and do not serve as either propulsion or load support sids. Controlled ground contact with skirt sections having special wearing surfaces may provide a suitable control method and would require the least significant change to the basic design of the vehicle or its components. The concept involves the use of an air flow control mechanism for defining specific skirt sections, thus causing skirt-ground contact at selected areas of the peripheral skirt.

TOPOLOGICAL PROPERTIES OF SOME TREL-LIS PATTERN CHANNEL NETWORKS.
Mock, S.J., Dec. 1976, 54p., ADA-034 824, 27 refs.

CHANNELS (WATERWAYS), TOPOGRAPHIC FEATURES, DRAINAGE, CLASSIFICATIONS. FEATURES, DRAINAGE, CLASSIFICATIONS.

The topological properties of 10 stream networks having moderate to well developed trellis drainage patterns have been compared with those expected in a topologically random population. Magnitude 4 subnetworks above a systematic departure from expectation which can be related to geological controls. A link type classification system was developed controls. A link type classification system was developed and a series of equations describing the probability of occurrence of link types in topologically random populations derived. Analysis of the link structure in the channel networks showed small but persistent deviations from expectation in the well developed trellis pattern streams. In general conclusion is that the topologically random model is a very useful standard with which to compare real channel networks.

CR 76-47 DEVELOPMENT OF LARGE ICE SAWS. Garfield, D.E., et al, Dec. 1976, 14p., ADA-034 899, 6 refs.

Hanamoto, B., Mellor, M. 32-1109

ICE CUTTING, SAWS.

This report describes two mechanical ice-cutting systems for the removal of ice collars at the high pool level on the Foe Lock of the St. Mary's Falls Canal at Sault Ste. Marie, Michigan. One system was a narrow-kerf (3 1/4 iz. wide) coel-cutting chain saw mounted on a bar, driven by a 65-hp wheeled soil trencher which cut a 0.56-in.

wide kerf. The lumber-curting saw's bar was too flexible and the desired cutting traverse speed was not met. The coal-cutting saw cut 6-ft-deep ice collars at traverse speeds of up to 10 ft/min and is acceptable. With a few modifications, the coal-cutting saw would be operational.

RAPID INFILTRATION OF PRIMARY SEW-AGE EFFLUENT AT FORT DEVENS, MASSA-CHUSETTS.

Satterwhite, M.B., et al, Dec. 1976, 34p., ADA-035 730, 26 refi

Stewart, G.L., Condike, B.J., Vlach, E.

GROUND GROUND WATER, WATER TREATMENT, WATER CHEMISTRY, SEWAGE TREATMENT. WATER CHEMISTRY, SEWAGE TREATMENT. Rapid inflitration has provided final treatment to unchlorinated minoff tank effluent at Fort Devens, Massachusetts, since 1942. Wastewater flow has varied seasonally; however, most flows to the 22 treatment beds at the installation in 1973 were 2,676 to 9,541 cu m/day (1.3 million gallons per day). In an operation cycle of simultaneous inundation of three 0,31-hecture treatment beds for 2 days, followed by a 14-day recovery period, affluent application has been about 27.1 m/yr. Chemical analyses of soil samples obtained from the upper 3.05 m of the treatment beds showed that levels of organic matter ranged from substantially to only alightly higher than those of background samples. The quality of the primary effluent applied to the treatment beds and the groundwater in 14 observation wells was determined by comprehensive analysis of the amplies at biweekly intervals. Oroundwater quality in wells located 60 to 100 m from the application area showed that the primary effluent after flowing through the send and gravel formation, had been substantially renovated.

CR 76-49 TREATMENT OF PRIMARY SEWAGE EFFLU-ENT BY RAPID INFILTRATION.

Satterwhite, M.B., et al, Dec. 1976, 15p., ADA-035 390, 22 refs. dike, B.J., Stewart, G.L.

32-1111 AGE TREATMENT, WATER TREATMENT. CHEMICAL ANALYSIS, SEEPAGE.

CHEMICAL ANALYSIS, SEEPAGE.

Treatment of unchlorinated primary sewage effluent by using rapid infiltration basins resulted in a high degree of wastewater renovation in a humid, cool northern climate. Inundating 9 treatment basins for 7 days followed by 14 days of rest, from 4 January to 21 June 1974, resulted in effluent additions totaling about 27 m. Analysis of the groundwater from the treatment site and from the peripheral sres showed that total colifform bacteria, 3-day biochemical crygen demand, and chemical caygen demand were essentially removed, while effluent concentrations. Total nitrogen additions to the treatment basins during the 7-day inundations period were shout 54% greater than the nitrogen additions in the 1973 investigations.

Even so, groundwater nitrogen concentrations were closely comparable to those observed in the 1973 study. Efforts to increase nitrogen removal through longer inundation periods resulted in a gradual decrease in the rightness of the basins. Calculation of the organic matter additions strongly suggested that the reduced infiltration capacities of the basins. Calculation of the organic matter additions strongly suggested that the reduced infiltration rates resulted from surface clogging. This study showed that proper management is needed if rapid infiltration basins are used for nitrogen removal by maintaining effluent infiltration in northern climates.

CR 77-01 GROWTH HISTORY OF LAKE ICE IN RELA TION TO ITS STRATIGRAPHIC, CRYSTAL-LINE AND MECHANICAL STRUCTURE.

Gow, A.J., et al, Jan. 1977, 24p., ADA-036 228, 9 refs Langston, D.

LAKE ICE, ICE GROWTH, ICE STRUCTURE, ELECTRICAL RESISTIVITY, CRYSTAL ORIEN-TATION, ICE MECHANICS.

TATION, ICB MBCHANICS.
Studies of the growth history and structural characteristics of winter ice covers on two New Hampshire lakes are described. These investigations included measurements of ice cover thickness, characterization of the strusignable and crystalline structure of the ice, identification and classification of major ice types and measurements of electrolytic conductivity. The formation of cracks and flaws in the ice and thereffects on the mechanical properties of the ice were also investigated. A method of correlating ice growth with surface wind and temperature measurement is described and the interrelationships of the various physical and mechanical properties of temperate lake ice covers are discussed. properties of temperate lake ice covers are discussed.

COMPUTER PROGRAM TO DETERMINE THE RESISTANCE OF LONG WIRES AND RODS TO NONHOMOGENEOUS GROUND

Arcone, S.A., Jan. 1977, 16p., ADA-036 250, 6 refs.

COMPUTER PROGRAMS, ELECTRICAL RESISTIVITY, MODELS, PROZEN GROUND PHY-SICS.

A computer program was developed for finding the resistance to ground of two simple electrodes, a strahorizontal wire and a vertically driven rod. The object of this study was to develop a rapid means of finding

resistance to ground of simple electrode types in arctic environments where a two-layer earth model, frozen and unfrozen ground, is applicable. The program can consider homogeneous as well as two-layer earth, and the length, diameter and position of the electrodes. Some specific computations are presented in comparison with previous theoretical work of other authors. The following conclusions were made:

1) A maximum run time of 165 aeconds is needed for all two-layer arctic models where (a) the depth of the upper layer does not exceed 10 m, (b) the vertical rod length is less than 30 m, or (c) the horizontal wire length is less than 100 m; 2) Best accuracy is obtained when rod and wire radii are less than 0.01 m; and 3) Coincidence of the center of the vertical electrode with the two-layer interface must be avoided.

EFFECT OF TEMPERATURE ON THE STRENGTH OF PROZEN SILT. Haynes, F.D., et al, Feb. 1977, 27p., ADA-037 932, 27

FROZEN GROUND STRENGTH, COMPRESIVE STRENGTH, SEDIMENTS, TENSILE STRENGTH, STRAINS, TEMPERATURE EPPECTS, PERMAPROST, TESTS.

FECTS, PERMAPROST, TESTS.

Tests were conducted in uniaxial compression and tension to determine the effect of temperature on the strength of frozen Fairbanks silt. Test temperatures ranged from OC to -56.7C. Two machine speeds, 4.23 cm/sec and 0.0423 cm/sec, were used for the constant displacement rate tests. Prom the highest to the lowest temperature, the compressive strength increased up to about one order of magnitude and the tensile strength increased one-half an order of magnitude and the tensile strength increased one-half an order of magnitude. Equations are presented which correlate strength with temperature at the strain rates obtained. The initial tangent and 50% strength moduli and the specific energy are given for each test. The mode of fracture and the effects of unfrozen water content and ice matrix strengthening are discussed, and the test results are compared with the data of other investigations.

CR 77-04 ST. MARYS RIVER ICE BOOMS. DESIGN FORCE ESTIMATE AND FIELD MEASURE-MENTS.

Perham, R.E., Feb. 1977, 26p., ADA-037 902, 13 refs. 32-1140

ICE BOOMS, RIVER ICE, ICE STRENGTH, ICE COVER STRENGTH, ICE LOADS, ICE NAVIGATION, UNITED STATES—ST. MARYS RIVER. TION, UNITED STATES—ST. MARYS RIVER. A set of two ice booms with a 250-ft (76m)-wide navigation opening between them was designed to stabilize the ice cover in the harbor at Sault Ste. Marie, Michigan and Ostario, and to reduce the ice losses associated with winter navigation of ships on the St. Marys River. The forces from natural effects on the ice cover were predicted using existing theory and physical dats for the area. The forces in the boom structure resulting from ice cover and boom interaction were estimated. When the ice booms were installed, force mess-present systems were put into selected anchor cables. These systems were operated all winter in conjunction with a modest program of supplemental data gathering. The force data exhibited periods when the force distribution was in good agreement with predictions and periods when the effect of ice on the booms differed substantially from predictions. Sometimes passing ships had a substantial effect on the ice cover and the boom loads, and at other times, the effect was negligible. The direction of travel made little difference on average peak loads. The maximum loads on the booms resulted from natural occurrences.

PERMAPROST, ELECTRICAL RESISTIVITY, SITE SURVEYS, VERY LOW FREQUENCIES, AIRBORNE RADAR, RADIO WAVES, ANAL-YSIS (MATHEMATICS).

YSIS (MATHEMATICS).

Airborne resistivity surveys, which use the wavetilt phenomena of radiowaves, are used as a preliminary exploration to chanique to find suitable areas for either engineering investigations or geologic reconnaissance explorations. Survey results are usually presented as resistivity flight like profiles or as contour maps from which the interpretation or site selection process must be initiated. To aid in this process and provide additional understanding of the correlation between data obtained from airborne and ground surveys, an analysis was performed to determine a very-low-frequency airborne system's response to toodelled resistivity anomalies assumed to occur at the surface of an idealized flat earth. Some of the assumptions used to simplify the analysis were based on the results of past surveys. The influences of survey altitude, assomaly size, and average ground resistivity upon airborne resistivity patterns were analyzed. The results show that the average resistivity of a region plays an important role in suppressing large resistivity contrasts for anomalies of approximately 1-eq km area. Curves are presented to separate the effects of resistivity contrast and anomaly size, and two examples are given to demonstrate how these curves may be applied to the results of actual surveys.

DEFENSIVE WORES OF SUBARCTIC SNOW. Johnson, P.R., Apr. 1977, 23p., ADA-051 769, 11 refs. 32-2725

SNOW (CONSTRUCTION MATERIAL), SNOW DENSITY, FORTIFICATIONS, MILITARY OP-**ERATION**

ERATION.
Pield tests at Fort Wainwright, Alaska, carried out in MarchApril 1975 showed that the typical subarctic snow of interior
Alaska can be used effectively to provide protection from
both rifle and mackine gun fire. The undisturbed snow
had an average density of 0.18 g/cu cm, but simple processing,
such as shoveling, increased the density to around 0.34
g/cu cm. Purther processing increased the density to
above 0.40 g/cu cm, but densities much shove that value
were difficult to obtain with simple hand equipment. Tests
of the M16 rifle and M60 and M2HB machine guns showed
that bullet penetration was inversely related to density—
the higher the density the lower the bullet penetration. Design values for the three weapons were determined. A

the higher the density the lower the bullet penetration. Design values for the three weapons were determined. A number of types of snow trenches and structures were designed and tested. They were found to provide good protection, in part since bullets showed a strong tendency to ricochet from the snow surface when striking it at a low angle. Burkep bags filled with snow to revet structures worked very well. Several types of Russian defensive works of snow were tested but proved unsuitable in the light, weak subscretic snow. The times required for troops to build several types of structures using only shovels and scoops were recorded. ral types of structu

MECHANICS OF CUTTING AND BORING. PART 4: DYNAMICS AND ENERGETICS OF PARALLEL MOTION TOOLS.

DRILLING, ROCK EXCAVATION, ICE CUTTING, BOREHOLE INSTRUMENTS, PERMA-FROST, METALS, DESIGN.

PROST, METALS, DESIGN.

The report deals with the cutting of rock and similar materials by parallel motion tools. It examines cutting forces and energy requirements, taking into consideration tool geometry, wear, operating conditions, and material properties. After an introductory discussion of terminology, some general principles are outlined, and relevant theoretical ideas on metal cutting and rock cutting are reviewed. The next section, which is the heart of the report, reviews experimental data on the magnitudes and directions of cutting forces. There is a graphical complication of deta, including some from obscure or unpublished sources. The variables covered include chipping depth, rake angle, relief angle, side rake, base angle, tool width, tool compliance, tool speed, tool wear, tool interactions, and material properties. The second major part of the report treats the energetics of cutting. It begins with a short discussion of relevant principles, and continues with a compilation and review of experimental data, covering the same independent variables as the force section. The report ends with a concise summary of general behavior for parallel motion tools.

CR 77-66 REMOTE SENSING OF ACCUMULATED FRA-ZIL AND BRASH ICE IN THE ST. LAWRENCE

n, A.M., Jr., Apr. 1977, 19p., ADA-039 905, 7 refs.

RIVER.

A broadbanded impulse radar system was used for serial detection of accumulated firail and brash ice in a 9.5-km reach of the St. Lewrence River near Ogden laland. The remote seesing and data reduction system developed for the project provided data sufficient for production of a contour map having 1-ft intervals. With this contour map, the accumulation pattern of frazil and brash ice could be analyzed. Recommendations are given for improving the performance of the serial profiling system.

ICE JAMS, ICE MECHANICS, ICE COVER STRENGTH, COMPRESSIVE PROPERTIES, ICE FLOES, ICE CONDITIONS, EXPERIMENTAL

This report presents experimental results on the conditions of initiation of an ice jam by a simple surface obstruction, on the equilibrium thickness of an ice jam formed by accumulation and submergence of ice floss, and on the compressive strength of a floating, fragmented ice cover. In the study on los jam initiation, it was found that the minimum concentration of floss in the opening of the obstruction at which a jam occurs is nearly independent of the ratio of width

of constricted passage to channel width and is proportional to a negative power of the ratio of floe length to width of constricted passage. The coefficient of proportionality and the negative exponent of this power function appear to be dependent upon the ratio of floe length to floe thickness and to be strongly affected by the properties of the material of the laboratory floes, in particular by the interparticle riction or coheave characteristics. From energy analysis of sigm formed by accumulation and submergence of floes and the approach flow characteristics was derived and found to fit the exparimental data satisfactorily. The relationship predicts that a stable jam cannot be formed when the approach flow velocity exceeds a certain value. This phenomenon was observed experimentally, and the measured maximum values of approach velocity were found to be in excellent agreement with the predicted values. In both studies on jam initiation and development, it was found that surface tension, and therefore the wetting properties of the material used for small laboratory floes, have a significant effect on the submergence velocity of small floes, and should be taken into consideration when small-cacle laboratory investigations of ice jam phenomena are conducted using floes made of artificial material. Experiments on compressive strength of floating, fragmented ice covers were conducted for ranges of cover length and cover thickness, using three different floe shapes and sizes. It was found that the compressive strength was inversely proportional to compressive strength and inversely proportional to compressive strength and independent of cover length. The effect of cover thickness and floe shape or size remains unclear partly because of the immitted ranges of thickness and floe size investigated and partly because of the experimental scatter in the results. ICE PRESSURE, PILE STRUCTURES, ICE BREAKING, ICE LOADS, ICE COVER THICKNESS, AIR TEMPERATURE.

NESS, AIR TEMPERATURE.

The amount of force that an ice sheet can apply to a vertical pile was tested by lowering a hydraulic ram device into a hole cut in an existing ice sheet. The device had a large base and shoved a relatively narrow vertical pile in a horizontal direction. Test variables were: pile widthe—1.5 in. to 36.7 in.; pile shapes—flat, round, 45 deg and 90 deg wedges; ice thickness—2.6 in. to 8.8 in.; and ram speed—0.07 in./sec to 18.75 in./sec; but not all shapes and sizes were tested at all speeds. Air tomperature was 20F (-6.7C). Forces and displacements were measured electronically. The findings are presented as a table of test results and as her graphs of the resultant ice pressures versus the pile width-to-ice-thickness ratio, pile width and hape combination and and pile velocity. The types of failures in the ice sheet were classified as crushing, splitting, buckling, bending, and croeping. The ice sheet generally withstood a high initial load followed by several lower peak load levels.

The maximum ice pressure measured was 610 psi for a 12.6-in.-diem round pile in 8.4-in.-thick ice. CR 77-11 CR 77-11

OBSERVATION AND ANALYSIS OF PROTECT-ED MEMBRANE ROOFING SYSTEMS. Schaefer, D., et al, Apr. 1977, 40p., ADA-040 220, 5

EFFECTIVENESS.

Two performance indicators, effectiveness and thermal efficiency, are defined and used to evaluate the year-round performance of three protected membrane roofs in Alsaka and New Hampshire. Effectiveness is a measure of the deviations of ceiling temperatures from a yearly average, with large deviation sindicating erratic performance in the roofing-insulation system. Thermal efficiency, the ratio of calculated heat loss to measured heat lose, is affected by climatic conditions such as rain, snow, solar radiation and wind. Thermal efficiency values of 100% or greater are possible since the calculated heat loss is based only on the inside and outside air temperature differences and the thermal properties of roof components. Results of the year-round evaluation indicate that the three protected membrane roofs generally have high values of both effectiveness and thermal efficiency. CR 77-12

McKim, H.L.

32-2699 REMOTE REMOTE SENSING, AERIAL SUR URBAN PLANNING, UNITED STATES— SACHUSETTS—BOSTON. SURVEYS.

SACHUSETTS—BOSTON.

The cost effectiveness of remote sensing techniques was compared to that of the conventional techniques used by the U.S. Army Engineer Division, New England, in the Boston Harbor-Bestern Massachusetts Metropolitian Area study. A total of 6 level I, 18 level II, and 18 level III land use categories were mapped from NASA RB-57/RC-8 high altitude aircraft photography for six selected 7.5 minute quadrangles located in the Boston area. Watershed and political boundaries could not be mapped from the NASA photography. Impervious surfaces and curb lengths were mapped from low altitude aircraft photography obtained with a Zeiss RMK 15/23 camera system (measured scale 1:3500) for two sites in the Boston South and Newton quadrangles. The remote sensing procedures were not always tout-effective when compared to the conventional procedures, but they were always more accurate. Therefore, remote to the conventions processive, but they were always more accurate. Therefore, remote sensing techniques should be used and appropriate photographic resolution and scale factors taken into consideration when mapping land use, curb density and impervious surfaces for use in the STORM (storage, treatment, overflow, runoff) model.

CR 77-14 ICE BREAKUP ON THE CHENA RIVER 1975 AND 1976.

ICE BREAKUP, RIVER ICE, DAMS, BRIDGES, FLOOD CONTROL, ICE COVER THICKNESS, ICE VOLUME, UNITED STATES—ALASKA—CHENA BRIDE CHENA RIVER

CHENA RIVER.

The breakup of the Chena River was observed and documented during the spring of 1975 and 1976. This study attempted to determine the potential for damage to the proposed Chena River flood control dam from ice and debris during breakup. Results of this study were compared to those of a 1974 companion study. In 1975, ice thicknesses were determined to be 15% thinger than in 1974 and ice volume was 33% smaller. No major ice floos were observed in 1975 and no significant flooding occurred, although the approaches to a bridge at the damnite were eroded by debris and high water immediately after breakup. The 1976 breakup was milder than that of 1975. Misnor flooding in the lower river was caused by jamming of a few large ice pieces, but no property damage resulted.

CR 77-15 EXPERIMENTAL SCALING STUDY OF AN AN-NULAR FLOW ICE-WATER HEAT SINE Stubstad, J.M., et al, June 1977, 54p., ADA-045 869,

ERIZED SIMULATION.

A laboratory experimental study was conducted on a scale model of an annular flow ice-water heat sink to be used to store the waste heat produced in a hardenad defense installation operating in an isolated mode. The study examined: 1) scaling relationships for predicting the performance of prototype units using data from scale models, 2) the accuracy of a computer prediction technique developed during an earlier study, 3) the heat transfer phenomenon at the ice-water interface, and 4) some practical sepects related to the operation of a prototype installation. The scaling relationships and the computer program were found to be sufficiently accurate for use in developing a prototype ink design. During operation the scale model sink provided an almost constant low temperature source of coolant water for approximately one-half its useful life and thereafter behaved like an ordinary stored water reservoir type heat sink. No significant operational problems were discovered.

ICEBREAKER SIMULATION. Nevel, D.B., July 1977, 9p., ADA-044 109, 6 refs.

ICEBREAKERS, ICE BREAKING, ICE NAVIGA-TION, MATHEMATICAL MODELS, SIMULA-TION

A brief discussion is given of the ways an icebreaker breaks ice. Since the icebreaking process is so complex, the solution of a mathematical model does not appear to be feasible. As an alternative, it is suggested that physical models be used to design icebreakers. The appropriate scaling laws for physical models are developed and thris measured. Imministration "discussion!"

CR 77-17 ACCUMULATION ON OCEAN STRUC-TURES.

Minsk, L.D. Aug. 1977, 42p., ADA-044 258, Bibliog-

raphy p.17-19. 32-1155

32-1153 ICE ACCRETION, ICE FORMATION, SHIP IC-ING, ICE PREVENTION, ICE REMOVAL, SEA SPRAY, AIR TEMPERATURE, WATER TEM-PERATURE, WIND FACTORS, FREEZING POINTS.

PERATURE, WIND FACTORS, FREEZING POINTS.

A literature search was made for information on the accretion of ice on ocean structures and on methods for control. The bulk of the reports were in Russian, with some additional Japanese, British, American, Canadian, and Icelandic sources. Analysis of icing reports indicated that sea spray is the most important cause of ahip icing, with lesser amounts due to freezing rain, mow, and fog. Icing is a potential danger whenever air temperatures are below the freezing point of water and the sea temperature is 6C or lower. Theoretical work on the ice accretion process is discussed, and a method is suggested, based on Russian experiments, for calculating the sea spray accumulation rate for cylindrical and flat surfaces as a function of water source temperature, air temperature, and wind speed. Other factors that influence icing severity are ship size and configuration, angle between ship course and water heading, and ship speed. Icing in the north temperate latitudes generally occurs in the rear of barometric depressions. Maps showing limits of various degrees of cing severity are included. Atmospheric icing measurements on tall land-based structures are presented, and potential maximum accumulations estimated. Control measures are discussed, though no completely effective method is available. Mechanical (impaction) methods are the most common, but experiments have been conducted on heated, icephobic, and deformable surfaces, and with freezing point depressents. No device for the unequivocal measurement of ice accumulation is available, though some experimental methods are suitable for controlled testing; it is recommended that a device be developed.

MODELS.

MODELS.

Models originally developed to describe the arching and the movement of granular materials through hoppers or chutes are applied to the arching and drift of pack ice in straits and gulfs having lengths of 50 to 500 km. Verification of the usefulness of the models is attempted by making comparisons with ice deformation patterns as observed via satellite imagery in the Bering Strait region and in Amundhen Culf. The results are encouraging in that there is good correspondence between observed arching and lead patterns and those predicted by theory. In addition, values determined via the model for the angle of internal friction (approx 30 deg to 35 deg) and the cohesive strength per unit thickness (approx 2,000N/m) are similar to values obtained by other approaches. It is estimated that if the wind velocity parallel to the Bering Strait exceeds approx 6 m/s, there will be ice flow through the strait. to the Bering Strait exceeds ice flow through the strait.

MECHANICS OF CUTTING AND BORING.
PART & DYNAMICS AND ENERGETICS OF
TRANSVERSE ROTATION ARCHINES. Mellor, M., Aug. 1977, 36p., ADA-045 127, 3 refs.

ROCK DRILLING, EXCAVATION, ICE CUTTING, DRILLS, PERMAFROST, DESIGN.

TING, DRILLS, PBRMAFROST, DESIGN.

The report deals with forces and power levels in cutting machines having a disc or drum that rotates about an axis perpendicular to the direction of advance. The forces on individual cutting tools are related to position on the rotor and to characteristics such as tool layout, roter speed, rotor size, machine advance speed, and rotor torque. Integration leads to expressions for force components acting on the rotor axis, taking into account tool characteristics, cutting depth of the rotor, and rotor torque. These provide estimates of tractive thrust and thrust normal to the primary free surface. For self-propelled machines, this leads to considerations of traction, normal reaction, weight and balance, and power/weight ratios. Specific energy consumption is analyzed and related to machine characteristics and strength of the material being cut. Power per unit working area is discussed, and data for existing machines are summarized. Power requirements for ejection of cuttings are analyzed, and the hydrodynamic resistance on underwater cuttings is treated. A number of worked examples are given to illustrate the principles discussed in the report.

INVESTIGATION OF AN AIRBORNE RESISTIVITY SURVEY CONDUCTED AT VERY LOW FREQUENCY.

MAINE—ALLAGASH.

An airborne survey of earth electrical resistivity, computed from the complex tilt of the electric field vector of a VLF (17.8 kHz) radio surface wave, has been studied. The survey was conducted at a 150-m mean flight altitude. The bedrock of the survey area was alate containing an igneous stock. Topography was found to distort the resistivity contours through its effect upon the vertical component of the electric field. At 300-m flight altitude most resistivity information was retained due to the deterioration of topographic influence. The phase of the tilt, which cannot be distinguished from the amplitude by an airborne antenna system, was determined from a ground survey of the surface impedance and was found to be an important influence on the airborne detection of high resistivity areas. The entire 150-m survey was reevaluated with topographic effects removed. The resolution of the igneous geology improved and several of these improvements were verified by the ground measurements.

32-1159 ROOFS, THERMAL INSULATION, COLD WEATHER CONSTRUCTION, COST ANALYSIS, ROOFS.

WEATHER CONSTRUCTION, COST ANALYSIS, UNITED STATES—ALASKA.

Cold weather limits the successful application of built-up roofing, but ofter a roof installation must be completed late in the fall or in the winter. The loose-laid protected membrane roof with a synthetic sheet membrane can be installed in the middle of the winter with complete reliability. A synthetic membrane is traditionally more expensive than built-up roofing (rising crude oil prices, however, have reversed this condition), but it has two special features besides its suitability for winter installation: it can be placed on a damp dect, if necessary, and, being loose-laid, it does not split because of deck movement. This report documents information on the installation of two roofs in Anchorage, Alaska, during January and February 1972, including a discussion of the necessary anow removal from the bare deck and the use of portable shelters for preparing the lap joints between sheets during very cold weather. The winter installation caused no special construction problems and the advantages of the synthetic membrane make it an attractive alternative to built-up roofing. The cost of loose-laid protected membrane roofs in Alaska was, in 1972, nearly \$300 per square (\$28/sq m), including insulation. Prices are rising as labor costs rise and as more insulation is specified. UNITED STATES—ALASKA.

MILITARY EQUIPMENT, SOIL STRENGTH, STATIC STABILITY, FOUNDATIONS.

STATIC STABILITY, FOUNDATIONS.

The results of field test programs conducted to evaluate the performance of several prototype baseplates on sand and clay soils are presented. One test series was accomplished to develop a possible alternative baseplate for the 60-mm Lightweight Company Mortar System (LWCMS). Three prototype baseplates were used in this series which resulted in design recommendations for a very lightweight, three-spade baseplate for use with the LWCMS. Another part of the program consisted of design and testing or prototype baseplate for use with an improved 81-mm mortar system. Design goals, which were verified in the test program, were to provide a displacement reduction of up to 30% and substantial reductions in tilt relative to the present M3 baseplate. Results obtained using a baseplate test fixture having spades of variable depth and configuration indicated that spade depth was very important on sand but of minor influence on clay. The influence of spade depth on displacement and tilt in both three- and four-spade configurations is covered in detail. Some data on the influence of socket height and perforation pattern on performance are also included.

This report discusses the relationship between an architect and a behavioral scientist. Some of the discussion applies

to this cooperative work for design of buildings. The bulk, however, relates to the cooperation of architect and behavioral scientist while conducting research. Rxamples from collaborative research at Alaskan military installations are cited which demonstrate the roles and contributions of the two disciplines.

EVALUATION OF EXISTING SYSTEMS FOR LAND TREATMENT OF WASTEWATER AT MANTECA, CALIFORNIA, AND QUINCY, WASHINGTON. Iskandar, I.K., et al, Sep. 1977, 34p., ADA-045 357, 28

refs. Murrmann, R.P., Leggett, D.C.

32-1161

WASTE DISPOSAL, GROUND WATER, SOIL CHEMISTRY, LAND DEVELOPMENT, WATER TREATMENT, ENVIRONMENTAL IMPACT.

CHEMISTRY, LAND DEVELUTIMENT, WALLES TREATMENT, ENVIRONMENTAL IMPACT.

Wastewater disposal sites at Manteca, California, and Quincy, Washington, were evaluated for their currer: performance and for the long-term impact of wastewater application. These sites have been operated as slow-infiltration, land-disposal systems for up to 20 years. Current performance was evaluated in terms of water quality, while soil chemical parameters were measured to determine the effects of protonged wastewater application at the sites. No significant effects on the performance were found to be due to differences in pretreatment. A difference between the performances of the two sites was attributed mainly to management practices, site history and climatic differences. While leaching of nitrate was observed at both sites, the impact on groundwater quality generally was found to be within the accepted limits (less than 10 mg/1 of NO3-N). Leaching of phosphorus to a depth of 150 cm was found at both sites but was higher at Manteca. This was thought to be due to problems associated with crop menagement, land use, and mode and schedule of wastewater application. Total and extractable phosphorus increased in the surface soil layers with time. However, soil nitrogen appeared to decrease, probably because of mineralization.

Soile increase in exchangeable Na was noted, but not enough to produce alkaline or saline capacity increased. Some increase in exchangeable Na was noted, but not enough to produce alkaline or saline conditions. A drop in soil pH at Quincy after prolonged application is thought to have been due to removal of carbonates by leaching and by H+ from nitrification. If these disposal areas were managed as treatment sites, leachate quality should meet proposed Environmental Protection Agency guidelines for drinking waters.

DETECTION OF MOISTURE IN CONSTRUC-TION MATERIALS.

Results of a study to determine the feasibility of using an impulse radar to detect moisture variations in the built-up roof at CRREL and to monitor the curing of concrete are presented. The results indicate that impulse radas are presented. Increases some that impuse risc can be used to detect wide variations in roof moisture associate with built-up roof surface deterioration and that this techniq has the potential of providing a nondestructive test metho-for measuring the strength of concrete during curing.

INTERMITTENT ICE FORCES ACTING ON IN-CLINED WEDGES.

Tryde, P., Oct. 1977, 26p., ADA-046 590, 15 refs.

ICE LOADS, LOADS (FORCES), ICE PRESSURE, WEDGES, ANALYSIS (MATHEMATICS), THEO-RIRS.

A theory for ice forces acting on inclined wedges has been developed, thus making it possible to predict the magnitude of the intermittent ice forces from knowledge of the physical parameters of the system. The theory has been verified by model tests with artificial and natural ice.

OBSERVATIONS OF THE ULTRAVIOLET SPECTRAL REFLECTANCE OF SNOW.
O'Brien, H.W., Oct. 1977, 19p., ADA-046 349, 11

32-1166 SNOW OPTICS, REFLECTIVITY, SPECTROPHO-TOMETERS, ULTRAVIOLET RADIATION.

TOMBIERS, ULTRAVIOLET KADIATION.
The spectral reflectance of natural snow in the range of 0.20- to about 0.40-micron wavelengths was studied in the laboratory using both continuous spectral scanning and fixed bandpass measurements. White barium suthists pressed powder was used as a standard for comparison. The reflectance of fresh snow was found to be very high (usually searly 100%) and only weakly wavelength dependent from 0.24 micron to the visible range. In the 0.20- to 0.24-micron portion of the spectrum, the reflectance was found to be quite erratic. Possible reasons for the irregularities in reflectance measurements are discussed.

CR 77-28 FREEZE-THAW TESTS OF LIQUID DEICING CHEMICALS ON SELECTED PAVEMENT MATERIALS.

Minsk, L.D., Nov. 1977, 16p., ADA-051 771, 7 refs.

FREEZE THAW TESTS, CHEMICAL ICE PRE-VENTION, CONCRETE DURABILITY, BITUMI-NOUS CONCRETES.

Tests were conducted to assess the extent of surface degradation resulting from the application of non-chloride decing chemicals on three types of airfield pavements. The chemicals tested were proprietary mixtures of urea, formamide, and ethylene glycol; sodium chloride, distilled water, and dry specimens were used as controls and for comparison. Pavements included new and old specimens of dense-graded asphaltic concrete. Portland cement concrete specimens used were new and old, with and without air-entrainment. New and old tar rubber concrete specimens were also tested. Samples were subjected to up to 60 freeze-thaw cycles with deicing chemicals flooding their upper surface. Each specimen was rated on a scale of 0-5 after every five freeze-thaw cycles. All PCC specimens showed some surface degradation, whereas the dense- and open-graded asphaltic concretes were largely unaffected. Tests were conducted to as es the extent of surface degra

INTERNAL STRUCTURE OF FAST ICE NEAR NARWAHL ISLAND, BEAUFORT SEA, ALAS-KA.

Gow, A.J., et al, Oct. 1977, 8p., ADA-047 785, 13 refs. Weeks, W.F. 32-2727

FAST ICE, ICE STRUCTURE.

PASI ICE, ICE STRUCTURE.

Results of measurements of salinity, grain size, substructure dimensions and crystal fabrics of the undeformed 2.15-m-thick annual sea ice sheet near Narwhal Island, Alaska, are presented. A notable observation was the formation of a dominant c-axis horizontal structure in all ice below 14 cm, including transformation to a pronounced east-west alignment of the c-axes by a depth of 66 cm. This study confirms earlier reports of the occurrence of very strong horizontal c-axis alignments in arctic fast ice.

COMPUTER MODEL OF MUNICIPAL SNOW

Tucker, W.B., Nov. 1977, 7p., ADA-047 360, 10 refs. 32-1630

SNOW REMOVAL, URBAN PLANNING, COM-PUTERIZED SIMULATION.

PUTERIZED SIMULATION.

A general computer model to simulate municipal snow removal has been developed. Programs which aid in the routing of snowplows are a part of this package. Once vehicle routes are created, the simulation program can be used to assess situations varying both equipment and meteorological parameters. Time for each plow to complete its route is calculated. Considerations are made for the above variable parameters plus plowing windrow, route starting depth, overlapping truck routes and intersection delay time. The effects of storm length, snowfall rate and starting depth on total plowing time are examined in a test case.

ROOF MOISTURE SURVEY: TEN STATE OF NEW HAMPSHIRE BUILDINGS.

Tobiasson, W., et al, Dec. 1977, 29p., ADA-048 986, 5 refs.

Korhonen, C., Dudley, T. 32-2695

ROOFS, WATER CONTENT, INFRARED PHO-TOGRAPHY.

Ten roofs in Concord, New Hampshire, were surveyed for wet insulation using a hand-held infrared camera. Suspected wet insulation using a hand-held infrared camera. Suspected wet areas were marked on the roof with spray paint and roof samples were obtained to verify wet and dry conditions. Recommendations for maintenance and repair were made based on infrared findings, water contents, and visual examinations. An incremental economic study is presented to serve as a guide in determining the most cost-effective approach.

CR 77-32 HEAT TRANSFER OVER A VERTICAL MELT-ING PLATE.

Yen, Y.-C., et al, Dec. 1977, 12p., ADA-049 437, 11 nefs.

Hart, M.M.

32-2696
HEAT TRANSFER, CONVECTION, ICE MELTING, WATER FLOW, EXPERIMENTAL DATA.
An experimental study of forced convective heat transfer
over a vertical melting plate has been conducted. This
study covers water velocities ranging from 1.7 to 9.8 mm/s
and bulk water temperatures from 1.11 to 7.50C. The
experimental results are correlated in terms of Nusselt, Prandit
and Reynolds aumbers with a moderate correlation coefficient
of 0.843. The results are expected to be useful in predicting
the heat transfer characteristics of a much larger prototype
ice-water heat sink. 32-2696 ice-water heat sink

CR 78-01 AXIAL DOUBLE POINT-LOAD TESTS ON SNOW AND ICE.

Kovacs, A., Mar. 1978, 11p., ADA-053 321, 11 refs. 32-3535

ICE MECHANICS, SNOW MECHANICS, COM-PRESSIVE STRENGTH, INDEXES (RATIOS), STRAIN TESTS, ANTARCTICA—MCMURDO SOUND.

SOUND.

The results of axial double point-load tests on disk samples of snow and ice obtained from the area of McMurdo Sound, Antarctica, are presented. They show the effects of temperature, sample length, load point diameter and specific gravity on failure load. It was determined that 13 samples should be tested to obtain a representative mean strength index. The results show that the axial double point-load test has good possibilities as a rapid field test for determining the unconfined compressive strength of snow and ice but that further evaluation of the variables affecting test results must be made. (Auth.) (Auth.)

SOME ELEMENTS OF ICEBERG TECHNOLO-

Weeks, W.F., et al, Mar. 1978, 31p., ADA-053 431, 52

Mellor, M. 32-3536

ICEBERG TOWING, ICE (WATER STORAGE), ENGINEERING.

ENGINEERING.
Many of the technical questions relating to iceberg transport are given brief, but quantitative, consideration. These include icebergs at sea, towing forces and tug characteristics, drag coefficients, ablation rates, and handling and processing the icebergs at both the pick-up site and at the final destination in particular, the paper attempts to make technical information on glaciological and ice engineering aspects of the problem more readily available to the interested planner or engineer. Specific conclusions include: 1) No unprotected iceberg, no matter how long or wide, would be likely to survive the ablation caused by a long trip to low latitudes. 2) Icebergs that have a horizontal dimension exceeding 2 km may well be prone to breakup by long wavelength swells. 3) To avoid the dangers associated with an iceberg capsizing, the width of a 200-m-thick iceberg should always be more than 300 m. 4) For towing efficiency the length/width ratio of a towed iceberg should be appreciably greater than unity. 5) For a pilot project, the selected iceberg would have to be quite small, if for no other reason than the practical availability of tug power. CR 78-03 BEARING CAPACITY OF RIVER ICE FOR VEHICLES.

Nevel, D.E., Apr. 1978, 22p., ADA-055 244, 7 refs. 33-2527

RIVER ICE. ICE STRENGTH. VEHICLES. FLOATING ICE.

The mathematical theory for the bearing capacity of river ice for vehicles is presented.

The floating ice aheet is assumed to have simple supports at the shore line. Solutions are presented for loads uniformly distributed over circular and rectangular areas. Numerical evaluations are made for a number of vehicles and the results presented in graphical

CR 78-04 COMPARISON BETWEEN DERIVED INTER-NAL DIELECTRIC PROPERTIES AND RADIO-ECHO SOUNDING RECORDS OF THE ICE SHEET AT CAPE FOLGER, ANTARCTICA. Keliher, T.E., et al, Apr. 1978, 12p., ADA-055 245, 17

refa Ackley, S.F.

32-4366

ICE SHEETS, ICE ELECTRICAL PROPERTIES, ICE PHYSICS, RADIO ECHO SOUNDINGS, DIE-LECTRIC PROPERTIES, ICE COVER THICK-NESS, ICE DENSITY, ANTARCTICA—FOLGER,

CAPE.

Measured physical properties of core to bedrock taken at Cape Folger, Bast Antarctica, are used to compute a profile of dielectric properties and from this, a depth-reflection coefficient profile for comparison with the observed radio-echo reflections. The measurements available on physical properties are: density variations, bubble size and shape changes, and crystal fabric variations. The close correspondence between the depths of the bubble shape changes (which are definitely deformational features), and the depths of the density variations, and between both of these and the radio-echo layers, indicates that deformational events in the ice sheet's history are represented by the variations in the physical property and associated radio-echo records. (Auth. mod.)

CR 78-05

VISCOELASTIC DEFLECTION OF AN INFI-NITE FLOATING ICE PLATE SUBJECTED TO A CIRCULAR LOAD.

Takagi, S., Apr. 1978, 32p., ADA-054 896, 19 refa. 32-4367

FLOATING ICE, PLATES, VISCOELASTICITY, LOADS (FORCES), ANALYSIS (MATHEMAT ICS).

The viscoelastic deflection of an infinite floating ice plate subjected to a circular load is solved, assuming the Maxwell-Voigt type four-element model. An effective method is developed for numerical integration of the solution integrals, of which each integrand contains a product of Bessel functions extending to infinity. The theoretical curve is fitted to the field data, but the material constants thus found varied

CR 78-06 SEGREGATION FREEZING AS THE CAUSE OF SUCTION FORCE FOR ICE LENS FORMA-

Takagi, S., Apr. 1978, 28p., ADA-054 217, 28 refs.

THEORIES, SOIL CREEP, PLASTIC DEFORMA-TION, BOUNDARY VALUE PROBLEMS.

TION, BOUNDARY VALUE PROBLEMS.

The theory of non-coaxial in-plane plastic deformation of soils that obey the Coulomb yield criterion is presented. The constitutive equations are derived by use of the geometry of the Mohr circle and the theory of characteristic lines. It is found that, for solving a boundary value problem, the non-coaxial angle must be given such values that enable us to accommodate the presupposed type of flow in the given domain satisfying the given boundary conditions. The non-coaxial angle is contained in the constitutive equations as a parameter. Therefore, the plastic material obeying the Coulomb yield criterion is a singular material whose constitutive equations are not constant with material but are variable with flow conditions.

CR 78-08 INTERACTION OF A SURFACE WAVE WITH A DIELECTRIC SLAB DISCONTINUITY.
Arcone, S.A., et al, Apr. 1978, 10p., ADA-055 956, 15

Delaney, A.J. 32-4369 ICE ELECTRICAL PROPERTIES, DIELECTRIC PROPERTIES, WAVE PROPAGATION, ELECTRIC FIELDS, MICROWAVES, AIRCRAFT ICING, HELICOPTERS, ICE REMOVAL.

ING, HELICOPIERS, ICE REMOVAL.

The interaction of a 51-GHz transverse electric surface wave with a dielectric slab is experimentally investigated. The wave is initially supported by a dielectric substrate resting upon a metallic ground-plane. A slab, made of the same dielectric material as the substrate and variable in height; is then placed upon the waveguide. The results for a small slab sitting on the substrate showed that the discontinuity was a very inefficient launcher of reflected surface waves. Investigations of these reflections with a trough waveguide. was a very inefficient launcher of reflected surface waves. Investigations of these reflections with a trough waveguide showed that, for values of slab height comparable to the exponential decay height of the surface wave, the reflections remain very small. However, as the slab height is increased beyond the decay height, the reflected amplitude approaches the theoretical value for a plane wave reflected from the interface between sir and the same dielectric. The results are applicable to surface wave methods of microwave deicing of wings and helicopter rotors.

CR 78-09 FLEXURAL STRENGTH OF ICE ON TEMPER ATE LAKES—COMPARATIVE TESTS OF LARGE CANTILEVER AND SIMPLY SUPPORT-ED BEAMS

Gow, A.J., et al, Apr. 1978, 14p., ADA-054 218, 9

Ueda, H.T., Ricard, J.A.

LAKE ICE, FLEXURAL STRENGTH, STRESS CONCENTRATION, SUPPORTS.

CONCENTRATION, SUPPORTS.

Large, simply supported beams of temperate lake ice were found, generally, to yield significantly higher flexural strengths than the same beams tested in the cantilever mode. Data support the view that a significant stress concentration may exist at the fixed corners of the cantilever beams. Maximum effects are experienced with beams of cold, brittle ice substantially free of structural imperfections; for this kind of ice the strength difference factor, here attributed to the effect of stress concentrations, may exceed 2.0; that is, simply supported beams test a factor of 2 or more stronger than the same beams tested in the cantilever mode. In ice that has undergone extensive thermal degradation, the stress

concentration effect may be eliminated entirely. Simply supported beams generally yield higher strengths when the top surfaces are placed in tension. This behavior is attributed to differences in ice type; the fine-grained, crack-free top layer of snow-ice, which constituted up to 50% of the ice cover in the current series of tests, usually reacted more strongly in tension than the coarse-grained crack-prone bottom labe less.

Shaw, K.A., Lemieux, G.

32-4370

WET SNOW, SNOW COMPRESSION, SNOW WATER CONTENT, VISCOSITY, SALINITY, SNOW MELTING, STRESSES, IONS.

SNOW MELTING, STRESSES, IONS.
The compressibility of wet snow is described in terms of pressure melting and nonlinear viacous deformation at grain contacts. The results of experiments with different salinities and liquid water contents are compared with computed densities. The decreasing compressibility of wet snow with increasing salinity and decreasing liquid content is quantified and explained. Simultaneous particle growth and the doubly charged layer at phase boundaries are included in the model. The results show that the density of wet snow increases approximately as a power of time but is highly dependent on the stress, initial particle size, liquid water content, and ionic impurity content of the snow.

CR 78-11

MECHANICS OF CUITING AND BORING. PART & DYNAMICS AND ENERGETICS OF CONTINUOUS BELT MACHINES.

Mellor, M., Apr. 1978, 24p., ADA-055 247. 32-4371

ROCK EXCAVATION, BOREHOLE INSTRU-MENTS, ROCK DRILLING, EXCAVATION, ICE CUTTING, MACHINERY, PERMAPROST, DE-SIGN.

The report deals with forces and power requirements for cutting machines of the belt type, as exemplified by large chain saws and isdder trenchers. The forces of single cutting tools are considered, and related to the overall forces on a cutter bar. Porces are related to power, and sources of loss are identified.

Tructive thrust and normal reaction and to assess the traction, weight and of loss are identified. Tractive thrust and normal reaction are analyzed and used to assess the traction, weight and balance factors for self-propelled machines. Specific energy consumption and performance index are treated, and concepts of power density and apparent belt pressure are introduced. Requirements for acceleration of cuttings are assessed, and the report concludes with a set of worked examples.

SOIL WATER MIGRATION.

SOIL WATER MIGRATION.
Road test sections of membrane-enveloped silt and clay soils overlain with asphalt cement concrete were subjected to repetitive dynamic plate-bearing loadings to determine their strength variations during freeze-thaw cycles. The recoverable surface deformations in the load deflection bowl were continuously measured during the loading cycles and analyzed, using the Chevron layered elastic computer program to obtain the in situ resilient deformation modulus of the various section layers at different stages of the freeze-thaw cycles. The resilient stiffness of the pavement system (the total load per unit of resilient load plate deflection) was also calculated for the various freeze-thaw conditions. The modulus values of the asphalt cement concrete varied inversely with its temperature by an order of magnitude (90,000 psi to 1,300,000 psi). The resilient stiffness of the pavement system varied in the same manner by nearly a factor of cight (22.4 kips/in. to 1740.2 kips/in.). Despite the wide strength variations of the sections during freeze-thaw cycles, membrane-enveloped fine-grained soils can be utilized instead of granular materials as base and subbase layers in flexible pavements in cold regions where moisture migration is a major concern. Moisture migration did not occur at saturation levels up to 75%; thus there was no strength loss during thewing.

CR 78-13

PREFERRED CRYSTAL ORIENTATIONS IN THE FAST ICE ALONG THE MARGINS OF THE ARCTIC OCEAN

Weeks, W.F., et al, June 1978, 24p., ADA-059 024, 77

refs. Gow, A.J.

SEA ICE, FAST ICE, ICE CRYSTAL STRUCTURE, OCEAN CURRENTS.

Peld observations of the growth fabrics of the fast and near-fast ice along the coasts of the Beaufort and Chukchi Seas above that, at depths of more than 60 cm below the upper ice surface, the sea ice crystals show striking alignments

within the horizontal plane. In general, the c-axes of the crystals were aligned roughly E-W parallel to the coast. In the vicinity of islands the alignment roughly paralleled the outlines of the islands, and in narrow passes between islands the alignment paralleled the channel. Our observations, as well as similar observations made in the Kara Sea by Cherepanov, can be explained if it is assumed that the c-axes of the crystals are aligned parallel to the "long-term" current direction at the sea ice/sea water interface. The slignments are believed to be the result of geometric selection among the growing crystals, with the most favored orientation being that in which the current flows normal to the plates of ice that make up the dendritic ice/water interface characteristic of sea ice.

BUCKLING PRESSURE OF AN ELASTIC PLATE FLOATING ON WATER AND STRESSED UNIFORMLY ALONG THE PERIPHERY OF AN INTERNAL HOLE.

Takagi, S., June 1978, 49p., ADA-056 585, 10 refs.

FLOATING ICE, ICE STRENGTH, BOUNDARY VALUE PROBLEMS, ANALYSIS (MATHEMAT-ICS).

ICS).

The analytical solution and the numerical study of the eigenvalue problem for determining the buckling pressure of an infinite clastic plate floating on water and stressed uniformly along the periphery of an internal hole is presented. The boundary conditions considered are the clamped, sincular, and free-edge conditions. Small buckling pressure scoper only for the free-edge condition. The shape of the deflection for the free-edge condition suggests that buckling is an important mechanism of failure.

ON THE DETERMINATION OF HORIZONTAL FORCES A FLOATING ICE PLATE EXERTS ON A STRUCTURE.

Kerr, A.D., Aug. 1978, 9p., ADA-060 444, 26 refs. For this report from a different source see 32-4451. 33-1521

PLOATING ICE, ICE PRESSURE, LOADS (FORCES), OFFSHORE STRUCTURES, ICE (FORCES), STRENGTH.

STRENGTH.

This report first discusses the general approach for calculating horizontal forces an ice cover exerts on a structure. Ice force determination consists of two parts: (1) the analysis of the in-plane forces, assuming that the ice cover remains intact, and (2) the use of a failure criterion, since an ice force cannot be larger than the force capable of breaking up the ice cover. For an estimate of the largest ice force, an elastic plate analysis and a failure criterion are often sufficient. A review of the literature revealed that, the majority of the analyses, it is assumed that the failure load is directly related to a "crushing strength" of the ice cover. However, observations in the field and tests in the laboratory show that in some instances the ice cover fails by buckling. This report reviews the ice force analyses based on the buckling failure mechanism and points out their abortcomings. The report then presents a new method of analysis which is based on the buckling mechanism.

HYDRAULIC MODEL INVESTIGATION OF DRIFTING SNOW.

Wuebben, J.L., June 1978, 29p., ADA-059 175 33-1767

HYDRAULIC STRUCTURES, SNOWDRIFTS, MODELS, BOUNDARY VALUE PROBLEMS, SNOW FENCES.

SNOW FENCES.

A model investigation of drifting snow conditions was conducted in a hydraulic flume using a sand-water analog. Model results were evaluated to define modeling parameters that would allow quantitative correlation between necessured protocype drift conditions and the model. Models of the fence were constructed for three heights and two geometric scales. Comercic scaling was based on terrain roughness and boundary layer thickness considerations, while velocity scaling was based on particle fall velocity and threshold of motion characteristics. Simulation of the atmospheric boundary layer was found to be of primary importance. Velocity scaling analysis suggested the use of a 'significant wind' concept, based on a combination of velocity magnitude and frequency. Similarity of precipitation rate was not essential, and could be altered within limits to adjust the time scale.

SHORELINE CHANGES ALONG THE OUTER SHORE OF CAPE COD FROM LONG POINT TO MONOMOY POINT

Gatto, L.W., July 1978, 49p., ADA-060 297, 52 refs.

SHORELINE MODIFICATION, AERIAL SUR-VEYS, PHOTOINTERPRETATION.

VEYS, PHOTOINTERPRETATION.

This investigation utilized historical and recent aerial photographs and satellite imagery in 1) estimating changes in positions of the high-water line and sea cliff break and sea; in rates of accretion and/or erosion, and in volumes of transported sediment, and 2) providing a preliminary evaluation of the direction of littoral transport along the outer Cape Cod coast. This investigation has illustrated a photo interpretation technique that is useful in performing a recontainsance of coastal change. The data obtained from this method can be used to supplement those acquired by ground

surveys and are valid as first approximations for planning subsequent, more detailed surveys.

BESTUARIES, SHORELINE MODIFICATION, REMOTE SENSING, AERIAL SURVEYS, SPACE-BORNE PHOTOGRAPHY, TIDAL CURRENTS, SEDIMENTATION, MAPPING.

BORNE PHOTOUGRAPHY, IIDAL CURRENTS, SEDIMENTATION, MAPPING.

The primary objective of this project was to demonstrate the utility of remote sensing techniques as an operational tool in the acquisition of data required by the U.S. Army Corps of Engineers, Seattle District, in the Grays Harbor dredging effects project, and related projects. Aerial imagery was used to map surface circulation and suspended sediment patterns near the hopper dredge pump site at the harbor entrance and near pulpmill outfalls in Aberdeen, and to map the areal distribution and extent of intertidal habitats. The surface circulation maps, prepared from the serial photographs and thermal imagery, compared favorably with the large-scale circulation patterns observed in the Grays Harbor hydraulic model at the U.S. Army Engineer Waterways Experiment Station.

Of the imagery provided by NASA, the thermal imagery was more useful than the color of color infrared (CIR) photographs for mapping circulation, while the CIR photographs were more useful than the thermal imagery or the color photographs for mapping intertidal habitats. Current velocities estimated from dye dispersion patterns and drifting dye drogues were comparable at some locations to velocities measured by in situ current meters and in the hydraulic model. Based on a cursory evaluation of LANDSAT-1 imagery sequired in January, February, and October 1973, it had limited utility in providing data on surface circulation patterns in Grays Harbor.

CR 78-19

PRIMARY PRODUCTIVITY IN SEA ICE OF THE WEDDELL REGION.
Ackley, S.F., et al, July 1978, 17p., ADA-059 344, 24

Taguchi, S., Buck, K.R. 33-1524

SEA ICE, ICE CORES, BIOMASS, WEDDELL SEA.

rnymeat and biological measurements were made of aca ice cores taken from 685 to 785 in the Weddell Sea. Fluorescence measurements indicated an algal community that was strongly associated with salinity maxima within the ice. Maximum concentration of chlorophyll a ranged from 0.306 to 4.54 mg/stere. Comparisons with the water column standing crop indicated that the standing crop within the ice represents a minor but significant percentage of the total standing crop for the region. The ice algal community is apparently distinct from others that have been described for land-fast ice in McMurdo Sound, sea ice in the Arctic and pack ice off Bast Antarctica. The highest concentrations of biological material are found in the bottom or top of the sample in those regions, whereas the Weddell Sea samples are concentrated at intermediate depths (6.5 m to 2.15 m) within the ice. A qualitative model indicating the relationship between thermally-induced brine migration and subsequent algae growth is presented. This model indicates the distribution of algae within the ice is dependent on the unique thermal and physical setting for Weddell Sea pack ice where brine drainage processes are initiated by spring and summer warming, but are not carried through as completely as in other regions. (Auth.) Physical and biological measurements were made of sea ice cores taken from 685 to 785 in the Weddell Sea. Pluores-

MEASUREMENT AND IDENTIFICATION OF AEROSOLS COLLECTED NEAR BARROW, AT.ASEA

Kumai, M., July 1978, 6p., ADA-058 606, 9 refs.

33-1525
ABROSOLS, PARTICLE SIZE DISTRIBUTION, ELECTRON MICROSCOPY.

BLECTRON MICROSCOPY.

Measurements of the concentrations of Aitken nuclei in maritime sir were made near Barrow, Alaska, in June 1975, with a modified Nolan-Pollack small-particle detector. The concentrations varied from 50 to 300 particles/cu cm, depending upon meteorological conditions. The mean Aitken nuclei count was 100 particles/cu cm for diameters greater than .002 microns. Transmission electron micrographs of serosols in maritime air near Barrow were taken. The rate range was measured to be 0.01 to 2.5 microns in diameter, with the most frequently observed diameter being 0.04 microns. The volume of the maritime air nod the collection efficiency were measured. The serosol concentrations were found to be 76 to 101 particles/cu cm. The aerosol particles in the maritime air were identified by electron microscopy and selected area electron diffraction analysis. About 20% of the aerosol particles were identified, and 80% of the particles were too small for electron diffraction analysis.

CR 78-21 ANALYSIS OF THE MIDWINTER TEMPERA-TURE REGIME AND SNOW OCCURRENCE IN

Bileilo, M.A., et al, Sep. 1978, 56p., ADA-066 934. Appel, G.C. 33-4415

AIR TEMPERATURE, SNOWFALL, METEORO-LOGICAL DATA, WEATHER FORECASTING, STATISTICAL ANALYSIS.

STATISTICAL ANALYSIS.
This study investigates the possibility of providing estimates of the time of occurrence and length of the freezing season for any location in East and West Germany by using the average January sir temperature (AJAT) as an index. The results indicate that reliable values of the mean freezing index can be obtained from the AJAT relationships which are developed for Germany. This association is further verified using data from the northeastern part of the U.S., and the AJAT is then used to determine the average starting and ending dates (and hence the probable length) of the freezing season for stations in Germany. The AJAT and the average dates of snowfall occurrence for numerous locations in the U.S. and Germany are also correlated. Interrelationships between these parameters and the average number of days with snow on the ground for stations up to 3000 m in elevation in Germany are examined.

UNDERSEA PIPELINES AND CABLES IN POLAR WATERS

Mellor, M., Sep. 1978, 34p., ADA-086 161. 19 refs.

PIPELINES, TRANSMISSION LINES, HYDRAU-LIC STRUCTURES, DAMAGE, ENGINEERING, EXCAVATION, SEA ICE, SUBSEA PER FROST, ICE SCORING, POLAR REGIONS.

Special environmental factors that influence the design, laying and maintenance of undersea pipelines and cables in polar waters are described. Various approaches to the protection and maintenance of undersea pipermes and cables in polar waters are described. Various approaches to the protection of submarine pipes and cables are considered, and prime emphasis is given to burial techniques for shallow water. A wide range of methods for treaching and burying are discussed, and technical data are given.

INFLUENCE OF FREEZING AND THAWING ON THE RESILIENT PROPERTIES OF A SILT SOIL BENEATH AN ASPHALT CONCRETE PAVEMENT.

Johnson, T.C., et al, Sep. 1978, 59p., See also 32-3761. Cole, D.M., Chamberlain, E.J. 33-3128

BITUMINOUS CONCRETES, SUBGRADE SOILS, SOIL FREEZING, GROUND THAWING, ELAS-TIC PROPERTIES.

TIC PROPERTIES.

Stress-deformation data for silt subgrade soil were obtained from in-seitu and laboratory tests, for use in mechanistic models for design of pavements affected by frost action. Plate-bearing tests were run on bituminous concrete pavements constructed directly on a silt subgrade, applying repeated loads to the pavement surface while the silt was frozen, tawing, thawed, and fully recovered. Repeated-load laboratory triaxial tests were performed on the silt in the same conditions. Analysis of deflection data from the in-situ tests showed resilient moduli of the silt as low as 2000 kPs for the critical thawing period, and 100,000 kPs or higher when silt was fully recovered. Analysis of the laboratory tests, which gave moduli comparable to the latter values, showed that resilient modulus during recovery from the thaw-weakened condition can be modeled as a function of the changing moisture content.

PERFORMANCE OF THE ST. MARYS RIVER ICE BOOMS, 1976-77.

am, R.E., Sep. 1978, 13p., ADA-061 431, 5 refs. 33-1526

ICE BOOMS, ICE PRESSURE, ICE NAVIGATION, COLD WEATHER PERFORMANCE.

TION, COLD WEATHER PERFORMANCE.

The ice booms on the St. Marys River at Sault Ste. Marie, Michigan and Ontario, were operated a second winter, 1967-77, under colder conditions, with less water flow, lower water levels, and 25% fewer ships in the river than during the previous year. The ice cover behind the booms remained frozen to shore for longer periods, and the loads registered in the booms were relatively unaffected by ship passages compared with the previous year's activity. As in the previous year, most structural load changes took place in the west ice boom and were due to movements of the ice cover immediately upstream of the boom. The cover broke free from shore on three occasions: the first and third occasions were minor events, but on the second occasion the cover cracked free, the timbers remained frozed to it, and the boom structure became damaged by the subsequent ice activity. Three anchor line assemblies broke over a period of about 4 hours; the two latter breaks occurred while a ship was operating in the ice. These events point out several factors to be considered in ice booms, such as designing the booms to withstand the action of the solid ice cover as well as the fragmented ice cover, keeping the structures and their assembly simple, and inspecting components and assemblies carefully.

CR 78-25 RIVER CHANNEL CHARACTERISTICS AT SE-LECTED ICE JAM SITES IN VERMONT. Gatto, L.W., Oct. 1978, 52p., ADA-061 778, 30 refs. 33-1527

ICE JAMS, CHANNELS (WATERWAYS), REMOTE SENSING, PHOTOINTERPRETA-TION, TOPOGRAPHIC FEATURES, RIVER ICE. The objectives of this investigation were to describe characteristics and geographic settings of ice jam sites from serial photographic interpretation, to indicate which characteristics may be important in causing ice jams, and to suggest additional uses of serial photographa. Uncontrolled photomosaics of each site were assembled and major river characteristics were delineated on the photomosaics. Characteristics described include: man-made structures, falls, rapids, changes in channel depths, channel islands, mid-channel should be the property of the changes in channel depths, channel islands, mid-channel shoals or bars, river bed material, river sinuosity, meanders, floodplain width, riparian vegetation, and types of development on the floodplain. River channel widths were measured from the photographs along rivers where ground truth data were available for comparison. Lengths of channel riffles and pools were measured along the rivers where variations in river depths were evident on the photographs. Acrial photographs provide a regional perspective for evaluating channel characteristics at an ice jams site and for analyzing the geographic setting at each site during ice-free conditions. Photographs taken after ice jams have formed are useful in monitoring ice jam formation, in analyzing ice characteristics, and in documenting ice jam breakup and movement.

CR 78-26 ICE FOG SUPPRESSION USING REINFORCED THIN CHEMICAL FILMS

McFadden, T., et al, Nov. 1978, 23p., ADA-063 107,

Collins, C.M. 33-2526

ICE FOG, FOG DISPERSAL, CHEMICAL ICE PREVENTION.

PREVENTION.

Ice fog suppression experiments on the Fort Wainwright Power Plant cooling pond were conducted during the winters of 1974-76. Baseline information studies occupied a sizable portion of the available ice fog weather in 1974-75. Then hexadecanol was added to the pond and dramatically improved visibility by reducing fog generated from water vapor released by the pond at -14C. Although this temperature was not low enough to create ice fog, the cold vapor fog created was equally as devastating to visibility in the vicinity of the pond. During the winter of 1975-76, suppression tests were continued, using films of hexadecanol, mixes of hexadecanol and octadecanol, and ethyleus glycol monobutyl ether (BGME). Suppression effectiveness at colder temperatures was studied and limits to the techniques were probed. A reinforcing grid was constructed that prevented breakup of the film by wind and water currents. Lifetime tests indicated the BGME degrades much more alowly than either hexadecanol or the hexadecanol-octadecanol mix. The films were found to be very effective fog reducers at warmer temperatures but still allowed 20% to 40% of normal evaporation to occur. The vapor thus produced was sufficient to create some ice fog at lower temperatures, but this ice fog occurred less frequently and was more quickly dispersed than the thick fog that was present before application of the films.

EFFECT OF TEMPERATURE ON THE STRENGTH OF SNOW-ICE.

Haynes, F.D., Dec. 1978, 25p., ADA-067 583. 33-4414

SNOW STRENGTH, ICE STRENGTH, TEMPER-ATURE EFFECTS, TENSILE PROPERTIES, COMPRESSIVE STRENGTH.

Uniaxial compression and tension tests were conducted on polycrystalline snow-ice to determine the effect of temperature Test temperatures ranged from -0.1C polycrystalline anow-ice to determine the effect of temperature on its strength. Test temperatures ranged from 0.1C - 54C. Two machine speeds, 0.847 mm/s and 84.7 mm/s were used for the constant displacement rate tests. The compressive strength at 54C was about one order of magnitude higher than at 0.1C. The tensile strength at -18C was about 20% higher than at -0.1C. The initial tangent and 50% strength moduli are given for the compression tests, while the secant modulus to failure is given for the tension tests. The mode of fracture is discussed and the test results are compared with data from other investigations.

TUNDRA DISTURBANCES AND RECOVERY FOLLOWING THE 1949 EXPLORATORY DRILLING, FISH CREEK, NORTHERN ALAS-KA.

Lawson, D.E., et al, Dec. 1978, 81p., ADA-065-192, 67 refs.

HUMAN FACTORS, ENVIRONMENTAL IM-PACT, OIL SPILLS, DAMAGE, EXPLORATION, TUNDRA VEGETATION, REVEGETATION.

A 1949 drill site in the Naval Petroleum Reserve Number 4, Alaska, the Fish Creek Test Well 1, was examined in August 1977 to determine the disturbance caused by drilling activities and to analyze the response and recovery of the

vegetation, soils, permafrost, and surficial materials to that disturbance. Man-made disturbances include bladed and unbladed vehicular trails, a winter runway, excavations, pilings, remains of camp structures, steel drums and other solid waste, and hydrocarbon spills. The most intense and lasting disturbance to the vegetation, soils, and permafrost resulted from bulledozing of surface materials, diesel fuel spills, and trails developed by multiple passes of vehiciae. Thermokarst subsidence and thermal erosion, caused by increased thaw of permafrost due to disturbance, resulted in the development of a hummocky topography and water-filled depressions at the drill site. Some ice wedges disturbed in 1949 are still metting. Soil disturbance ranges from suinor modification to complete destruction of the soil morphology. The effects of hydrocarbon spills are still destretable in the soils. Little of the original vegetation remains in the intensety disturbed area, such as around the drill pad where a grass-dominated community prevails. After 28 years, the vegetation cover is closed over most mesic sites, shallow wet sites are well vegetated, and zeric sites, areas of diseel fuel spills and areas of severe erosion remain mostly bare. Pioneering plant species on bare, disturbed areas are members of mature vegetation assemblages from the undisturbed under which have high reproductive and dispersal capacities. A hypothetical model of natural revegetation and vegetation recovery is proposed. Vescular plants, bryophytes, and lichens were collected from the Fish Creek site area for the first time. Recommendations on cleanup and restoration of sites are presented. of sites are prese

CR 79-01 STUDY OF WATER DRAINAGE FROM CO-LUMNS OF SNOW.

Denoth, A., et al, Jan. 1979, 19p., ADA-066 935. Seidenbusch, W., Blumthaler, M., Kirchlechner, P., Ambach, W.

SNOW, WATER FLOW, DRAINAGE.

Experiments were conducted to study the flow of water through columns of homogeneous, repacked snow. The gravity flow theory of water flow through snow was verified, although possibly there is some dependence of the relative permeability on the state of metamorphism of the snow. Also, at very large values of saturation there may be some additional flow in saturated channels.

CR 79-02 EFFECT OF WATER CONTENT ON THE COM-PRESSIBILITY OF SNOW-WATER MIXTURES. Abele, G., et al, Jan. 1979, 26p., ADA-066 936, 6 refa. Haynes, F.D. 3650

SNOW WATER CONTENT, SNOW COMPRESSION, SNOW DENSITY, SNOW DEFORMA-TION.

The stress-density relationships of snow-water mixtures were investigated and are shown as functions of water content, initial snow-water mixture density and rate of deformation. An increase in water content in rate of decormation. An increase in water content is snow at a particular density or a decrease in the rate of deformation (or strain rate) decreases the stress, but apparently not the specific energy required to reach a specific mixture. e in the rate of density.

CR 79-03 BLANK CORRECTIONS FOR ULTRATRACE ATOMIC ABSORPTION ANALYSIS. Cragin, J.H., et al, Jan. 1979, 5p., ADA-066 979, 2

refs.

Quarry, S.T. 33-3166 WATER CHEMISTRY, CHEMICAL ANALYSIS, METALS, ATOMIC ABSORPTION.

MBTALS, ATOMIC ABSORPTION.

Both flame and flameless atomic absorption(AA) measurements require a distilled water blank correction. This correction is due to the enalyte contained in the distilled water used to prepare the standards and not, as commonly thought, to the reference "blank" used to zero the instrument. Flameless AA analyses of acidified beavy metal samples generally require additional corrections for the furnace deflection blank and for an acid blank. To prevent adsorption losses, the said blank should be determined by extrapolation of a series of acid dilutions in distilled water.

COMPUTER MODELING OF ATMOSPHERIC ICE ACCRETION. Ackley, S.F., et al, Mar. 1979, 36p., ADA-068 582, 25

Templeton, M.K. 33-3651

refs.

ACCRETION, METEOROLOGICAL FAC-TORS, ICE PHYSICS, HELICOPTERS.

TORS, ICE PHYSICS, HELICOPTERS.

A computer model is described to compute the amount of ice accretion on an object under a variety of initial conditions. Numerical techniques are best applied to these problems because of time dependent effects governing the amount of ice collected and the variety of initial conditions that can lead to ice accumulation. The helicopter rotor icing problem adds an additional complexity since the velocity along the rotor blade varies over a wide range, strongly affecting the amounts of ice collected at different blade positions. The physics of ice accretion is reviewed, and the accounting for the time-dependence in the computer model is described.

Some model results are presented

and indicate the dependence of ice accretion on velocity, droplet sizes, cloud liquid water content, and temperature for a cylindrical object of constant size.

GROUTING SILT AND SAND AT LOW TEM-PERATURES—A LABORATORY INVESTIGA-

n, R., Mar. 1979, 33p., ADA-068 741, 4 refs. 33-3867

TEMPERATURE TESTS, GROUTING, ICAL REACTIONS, COMPRESSIVE LOW STRENGTH.

This report presents data from an experimental program undertaken to develop information on proposed and existing chemical grout solutions to provide engineering properties in connection with grouting of soils in ambient temperatures of 39 F and below. Twelve grout solutions were investigated, including organic chemicals, sodium silicates, cements, and clay (beatonite).

tive plate bearing (RPB) tests were at sections in state highways in M structive rep ducted on various test sections in state highwa during April 13-15, 1976. The RPB test consis during April 13-15, 1976. The RPB test consists of making resilient surface deflection measurements during repetitive loadings at various radii from the load plate. The pavement system stiffness was calculated, and the resilient modulus values for the various pavement layers were determined with the Chevron computer program for a layered elastic system. A thawed analysis using nondimensional deflection curves for the various sections provided a guide to the susceptibility of the pavement systems to surface failure and pothole development. Some comparisons between stabilized and nonstabilized aggregate and soil were made with calculated stiffness values. The moduli of the various materials were also compared. The residual surface deflections during testing for several pavement systems indicated ts of makins calculated stiffness values. The moduli of the various materials were also compared. The residual surface deflections during testing for several pevennent systems indicated a linear logarithmic relationship with number of load applications. A relationship between the modulus of the asphalt coment concrete pavement and pavement temperature was cement concrete pavement and pavement temperature was developed for the limited temperature range during the testing.

CR 79-07 PENETRATION TESTS IN SUBSEA PERMA-FROST, PRUDHOE BAY, ALASKA.

SUBSEA PERMAPROST, BOTTOM SEDIMENT, PENETRATION TESTS, PENETROMETERS, PENETRATION TESTS, OFFSHORE DRILLING.

OFFSHORE DRILLING.

Sediments beneath the Beaufort Sea near Prudhoe Bay, Alaska, were probed at 27 sites using a static cone penetrometer to determine engineering properties and distribution of material types, including ice-bonded sediments. The probe provided both point and casing resistance data and thermal profiles. At five sites these data were correlated with information from adjacent drilled and sampled holes. These control data and the quality of the probe information permitted profiles of sediment type and occurrence of ice-bonded material to be developed along three lines that included various geological features and depositional environments. Material properties were quite variable in the upper 14 m of sediments probed. In general, softer, finer-grained sediments occurred to the upper layers, while penetration refusal was met in stiff gravels 10 to 12 m below the seabed. Seabed temperatures during the study were all below OC. However, because of uncertainties in freezing point values caused by brines, evaluation of the penetration resistance data was required to identify the occurrence of ice-bonded sediments. The coupling of thermal and penetration resistance data was required that seasonally ice-bonded sediments occurred where the sea ice froze back to or near the seabed. Deeper, perennially frozen sediments also appeared to be present at several probe sites. The penetration data obtained can be used to aid in the design of shallow and deep foundations in both ince-bonded and unfrozen subsea sediments. ents beneath the Beaufort Sea near Prudhoe Bay, Alaska

SEA ICE RIDGING OVER THE ALASKAN CON-TINENTAL SHELP.

Weeks, W.F., Frank, M.

SEA ICE DISTRIBUTION, PRESSURE RIDGES, ICE DEFORMATION, SURFACE ROUGHNESS, PROFILES, LASERS, MATHEMATICAL MOD-ELS, STATISTICAL ANALYSIS, REMOTE SENS-ING, FORECASTING.

See ice ridging statistics obtained from a series of laser surface roughness profiles are examined. Each set of profiles consists of six 200-km-long flight tracks oriented approximately perpendicular to the coastline of the Chukchi and Beaufort

Seas. The flights were made in February, April, August, and December 1976, and one additional profile was obtained north of Cross Island during March 1978. It was found that although there is a systematic variation in mean ridge height (h) with season (with the highest values occurring in late winter), there is no systematic spatial variation in at a given time. The number of ridges/km is also high during the late winter, with the highest values occurring in the Berter and Cross Island profiles. In most profiles, the ice 20 to 60 km from the coast is more highly deformed than the ice either neaver the coast or further seaward. The Wadhams model for the distribution of ridge beights gives better agreement with observed values in the highest of the spatial recurrence frequency of large pressure ridges are made by using the Wadhams model. Estimates of the spatial recurrence frequency of large pressure ridges are made by using the Wadhams model and also by using an extreme value approach. In the latter, the distribution of the isrgest ridges per 20 km of leser track was found to be essentially normal. Wadhams' distribution consistently predicts slightly larger ridge sails than does the extreme value approach.

CR 79-89 SEDIMENTOLOGICAL ANALYSIS OF THE WESTERN TERMINUS REGION OF THE MATANUSKA GLACIER, ALASKA.

Lawson, D.E., May 1979, 112p., ADA-072 000, Refs. p.109-112.

GLACIAL DEPOSITS, GLACIAL GEOLOGY, SEDIMENT TRANSPORT, GLACIAL TILL.

SEDIMENT TRANSPORT, GLACIAL TILL. Sedimentation at the terminus of the Matanuaka Glacier has been found to be primarily subserial in a 100- to 300-m wide, ico-cored zone paralleling the edge of the active ice. Certain physical and chemical characteristics of the ice and debris of the superglacial, englacial and basal zones of the glacier indicate the debris of the basal zone, the primary source of sediment, is entrained during freeze-on of meliwater to the glacier sole. Till formation results from the melting of buried ice of the basal zone. Meltout till inherits the texture and particle orientations of basal ice debris; other properties are not as well preserved. Most deposits result from resedimentation of till and debris by sediment gravity flows, meltwater sheet and rill flow, slump, spall, and for ablation. Depositional processes are interrelated in the process of backwasting of ico-cored alopes. Sediment flows are the primary process of resedimentation. Their physical characteristics, multiple mechanisms of flow and deposition, and characteristics of their deposits vary with the water content of the flow mass. Deposits of with the water content of the flow mass. Their physical characteristics, multiple mechanisms of flow and deposition, and characteristics of their deposits vary with the water content of the flow mass. Deposits of each process are distinguished from one another by detailed analysis of their internal organization, geometry and dimen-sions, and the presence of other internal and related external features. Genetic facies are defined by these characteristics. CR 79-10

ULTRASONIC VELOCITY INVESTIGATIONS OF CRYSTAL ANISOTROPY IN DEEP ICE CORES FROM ANTARCTICA.

PROPERTIES, ANTARCTICA—BYRD STATION, ANTARCTICA—LITTLE AMERICA STATION. Lo cores from Byrd Station and Little America V have been used to test an ultrasonic technique for evaluating crystal anisotropy in the Antarctic Ice Sheet. P-wave velocities measured parallel and perpendicular to the vertical axes of cores from the 2164-m-thick ice sheet at Byrd Station have yielded results in excellent agreement with the observed c-axis fabric profile and with the in-situ P-wave velocity profile measured parallel to the bore hole axis. Velocity differences in excess of 140 m/s for core samples from deeper than 1300 m attest to the strong single pole clustering of crystallographic c-axes about the vertical especially in the zone from 1300-1800 m. Such oriented structure is compatible only with strong horizontal shearing in the zone. The existence in an ice sheet of widespread shearing several hundred meters above its bed raises serious questions as to the validity of current concepts of the flow of large ice masses that tend to gloss over or ignore crystal alignments of this magnitude. The ultrasonic technique has proven to be a fast and powerful tool for determining crystal fabrics in ice sheets. Results from Byrd Station and Little America V, together with fabric data from several other locations in Bast Antarctics, suggest that crystal orientations within the Antarctic Ice Sheet tend to be characterized by either single or multi-pole clustering of c-axes about a vertical symmetry axis.

CR 79-11 SNOWPACK OPTICAL PROPERTIES IN THE INFRARED.

erger, R.H., May 1979, 16p., ADA-071 004.

34-1366 SNOW OPTICS, SNOW DENSITY, LIGHT SCAT-TERING, REFLECTIVITY.

A theory of the optical properties of snow in the 2-20 microns region of the infrared has been developed. Using this theory, it is possible to predict the absorption assattering coefficients and the emissivity of snow, as function

of the snow parameters of grain size and density, for densities between 0.17 and 0.4 g/cu. cm. The absorption and acattering coefficients are linearly related to the density and inversely related to the average grain size. The emissivity is independent of grain size and exhibits only a weak dependence.

POINT SOURCE BUBBLER SYSTEMS TO SUP-PRESS ICE.

DETECTION OF ARCTIC WATER SUPPLIES WITH GEOPHYSICAL TECHNIQUES. Arcone, S.A., et al, June 1979, 30p., ADA-072 157, 38

Delaney, A.J., Sellmann, P.V.

WATER SUPPLY, DETECTION, GROUND WATER, MAGNETIC PROPERTIES, RADIO WAVES.

This report discusses the application of several modern geo-physical techniques to groundwater exploration in areas of permafrost. These methods utilize the principles of magnetic induction and radiowave surface impedance in the 10- to 400 kHz band, the techniques of impulse and side-looking radar in the 50- to 10,000 MHz band, and also some optical radar in the 50- to 10,000 MHz band, and also some optical techniques using imagery obtained from a satellite, all for detecting free water under an ice cover in shallow, almost completely frozen lake basins, and thaw zones within lake beds, stream channels, and in permathost in general. The radar studies demonstrate the use of these techniques for determining depth of free water and ice cover thickness on lakes and rivers.

34-134
SOIL FREEZING, COLD WEATHER TESTS,
FROST PROTECTION, SOIL WATER, WATERPROOFING, FROST HEAVE.

In 1973 two membrane encapsulated soil layer (MESL) test sections were constructed into existing gravel surfaced roads at Elimendorf AFB and at Ft. Wainwright in Anchorage and Pairbanka, Alaska, respectively. The Elmendorf AFB MESL contains a sity clay soil and the Ft. Wainwright MESL contains a nonplastic silt. Both sections were con-

structed at soil moisture contents of approximately 2% to 3% below optimum for the CE-12 compactive effort. There were no indications of soil moisture migration during freezing in either test section, and after-thaw field California Bearing Ratio values were nearly equal to values measured before freezing. There is prowing evidence of a slight increase in the overall soil moisture content in the Elmendorf AFB MESL, possibly from moisture entering through the single layer polyethylene sidewalls which were not treated with asphalt emulsion. There is good evidence that the membrane of the same section might have received damage during a soil sampling operation which allowed localized moisture infiltration. A two-layer polyethylene membrane used in the Pt. Wainwright MESL is considered a more positive moisture barrier than the single sheet and a justifiable added cost for permanent construction. structed at soil moiss 3% below and cost for permanent construction.

ROOF RESPONSE TO ICING CONDITIONS. Lane, J.W., et al, July 1979, 40p., ADA-074 477, 12

Marshall, S.J., Munis, R.H. 34-625

ROOPS, THERMAL CONDUCTIVITY, ICING, MELTING, SLOPE ORIENTATION.

MBLTING, SLOPE ORIENTATION.

Six test roofs of two different slopes—16.3 deg and 39.8 deg, and three different roof coverings—asphalt shingles, codar shingles, and corrugated aluminum sheeting, were constructed at USACRREL, Hanover, New Hampshire, and were instrumented with thermocouples, heat flow meters, and calibrated gutters. Measurements were recorded for the winters of 1971-72 and 1972-73. The degree of icing and the chronological changes in the snow cover were recorded on 35-mm Kodachrome slides. It was found that eave icing is a sensitive function of the slope, roof covering composition, and solar radiation. The effects of wind were not investigated; the data were screened to remove all information corresponding to windspeeds over 8 km/h. In order of increasing tendency to form ice dams on the caves, the roofs were high-slope asphalt, high-slope codar, high-slope aluminum.

CR 79-18

INSULATING AND LOAD-SUPPORTING PROPERTIES OF SULFUR FOAM FOR EXPEDIENT ROADS IN COLD REGIONS.

Smith, N., et al, Sep. 1979, 21p., ADA-074 694, 6 refs. Pazsint, D.A. 34-742

ROADS, THERMAL INSULATION, CELLULAR MATERIALS, BEARING STRENGTH, FREEZE THAW CYCLES.

THAW CYCLES.

Temperatures of the subgrade and of sulfur foam insulation test sections in an expedient road were monitored with thermocouples to document freezing and thawing conditions. Vehicular trafficking was conducted on a limited basis to determine the load supporting capabilities of the foam. The sulfur foam, placed directly under a prefabricated surface mat, was found to be unsuitable for use as an expedient thermal insulation and traffic load supporting material, primarily because of its low tensile strength and high brittleness. The insulating value of sulfur foam produced by the batch process in the field was about one-half that of extruded polystyrene, meaning double the thickness for equal protection against thaw. nst thaw.

CRITICAL VELOCITIES OF A FLOATING ICE PLATE SUBJECTED TO IN-PLANE FORCES AND A MOVING LOAD.

Kerr, A.D., Aug. 1979, 12p., ADA-075 455, 6 refs.

FLOATING ICE, DYNAMIC LOADS, VELOCI-TY.

The critical velocities of loads moving over floating ice plates have been determined by several authors. In all these analyses it was assumed that the in-plane force fleid in the ice cover is zero. However, due to constrained thermal strains, in-plane forces do occur in the field. The purpose of the present paper is to determine their effect upon the critical velocities of the moving loads. It is shown that a uniform compression force field reduces the critical velocity, whereas a tension force has the opposite effect

VOLUMETRIC CONSTITUTIVE LAW FOR SNOW SUBJECTED TO LARGE STRAINS AND STRAIN RATES.

Brown, R.L., Aug. 1979, 13p., ADA-075 474, 10 refs. 34-913

SNOW DEFORMATION, SNOW COMPRESSION, VOLUME, STRAINS, STRAIN TESTS, DYNAMIC LOADS, TRACKED VEHICLES.

NAMIC LOADS, TRACKED VEHICLES.

A volumetric constitutive equation was developed to characterize the behavior of snow subjected to large compressive volumetric deformations. By treating the material as a suspension of air voids in a matrix material of polycrystalline ice, a rate-dependent volumetric constitutive law was formulated and found to accurately predict material response to pressure loads for a wide range of load rates. Comparison of the theory with shock wave data was not considered in this paper, sithough the constitutive law appears to be valid for such load situations. One application to oversnow

mobility of tracked vehicles was made. In this case, power requirements due to snow compaction were calculated parametrically in terms of vehicle speed, track loading, and snow

CR 79-21 TOWING SHIPS THROUGH ICE-CLOGGED CHANNELS BY WARPING AND KEDGING. Mellor, M., Sep. 1979, 21p., ADA-077 801, 6 refs. 34-1380

Mentor, M., Sep. 1979, 21p., ADA-077 801, 6 rens.
34-1380
CHANNELS (WATERWAYS), ICE COVER, ICE PRESSURE, SHIPS, ANCHORS.
The report studies the question of whether Great Lakes freighters could move effectively through ice-clogged channels with the sid of tows provided by warping or kedging systems.
Ten operational concepts are outlined, and their advantages and disadvantages are noted. The crushing resistance of floating brash ice is then analyzed. The neutral, active and passive states of stress for laterally confined brash ice are considered, and the resistance to horizontal thrusting by a smooth vertical wall is calculated for cobesionless brash ice, and for ice in which there is finite cohesion between the ice fragments. The thickening of the ice cover in the vicinity of a "pusher" and the formation of pressure ridges are analyzed in order to estimate the amount of pile-up that can occur against a ship hull. The analysis then moves on to consideration of ship resistance by brash ice, taking into account crushing resistance at the bow, angential friction at the bow, and the hull friction aft of the bow section. Comparisons are made between thrust from the ship's screws and the calculated ice resistance. The next section of the report estimates the force requirements from the ship's acrews and the calculated ice resistance. The next section of the report estimates the force requirements for a warping or kedging system in terms of throut augmentation for existing vessels. Tow cable requirements are given, and estimates are made for cable anchors and for anchorage of underwater structures. The force and power requirements for winches and windlasses are given, the practical problems involved in the pickup or transfer of cables are mentioned, and the report concludes with a brief appraisal. The conclusion is that a simple warping tug system is appropriate for a full-scale experiment, a chain ferry with auxiliary barge seems attractive for an operational system, and a chain ferry plow may be an efficient way to clear ice from channels.

CR 79-22 CRYSTAL ALIGNMENTS IN THE FAST ICE OF

ARCTIC ALASKA Weeks, W.F., et al, Oct. 1979, 21p., ADA-077 188, 9

refs.

Gow, A.J. 34-1379

ICE CRYSTAL STRUCTURE, FAST ICE, ICE CRYSTAL GROWTH, SEA ICE, OCEAN CUR-RENTS.

RENTS.
Field observations at 60 sites located in the fast or near-fast ice along a 1200-km stretch of the north coast of Alaska between Bering Strait and Barner Island have shown that 95% of the ice samples exhibit striking c-axis alignments within the horizontal plane. Such alignments were usually well developed by the time the ice was 50 cm thick. In all cases the degree of preferred orientation increased with depth in the ice. Representative standard deviations around a mean direction in the horizontal plane are commonly less than 10 deg for samples collected near the bottom of the ice. The general patterns of the alignments support a correlation between the preferred c-axis direction and the current direction at the ice/water interface. A comparison between c-axis alignments and spot current measurements made at 42 locations shows that the most frequent current direction coincides with the mean c-axis direction. Such alignments are believed to be the result of geometric selection with the most favored orientation being that in which the current flows normal to the (0001) plates of ice that compose the dendritic sea ice/sea water interface.

EFFECTS OF SEASONAL CHANGES AND GROUND ICE ON ELECTROMAGNETIC SUR-

VEYS OF PERMAPROST.
Arcone, S.A., et al, Oct. 1979, 24p., ADA-077 903.
Delaney, A.J., Sellmann, P.V.

34-2363 PERMAFROST DISTRIBUTION, ELECTRO-MAGNETIC PROSPECTING, SEASONAL VARIATIONS, GROUND ICE.

VARIATIONS, GROUND ICE.

The performance of surface impedance and magnetic induction electromagnetic subsurface exploration techniques was studied seasonally at various sites in Alaska where permafrost and massive ground ice occurred. The methods used have greatest sensitivity within about 20 m of the surface and are, therefore, most applicable for shallow subsurface investigations. The selection of study sites was based on anticipated contrasts in electrical resistivity between ground ice and conjunct and adjacent earth materials. A magnetic induction instrument, using a separation of 3.66-m between the transmitter and receiver antennas, in general was able to detect near-surface zones of massive ice and to provide data regarding permafrost distribution in both the Pairbanks and Prudhoe Bay areas.

ANTIFREEZE-THERMODRILLING FOR CORE THROUGH THE CENTRAL PART OF THE ROSS ICE SHELF (J-9 CAMP), ANTARCTICA. Zotikov, I.A., Nov. 1979, 12p., ADA-078 748, 11 refs.

ICE SHELVES, ICE CORES, DRILL CORE ANAL-

YSIS.

By using a new thermocoring technique, a hole was successfully drilled through the 416-m thickness of the Ross Ice Shelf at J-9 Camp. This report provides a description of the drill and an socount of this drilling project. A provisional examination of the core shows the ice shelf to consist of 410 m of snow and glacial ice undertain by 6 m of sea ice formed by direct freezing of sea water to the bottom of the Ross Ice Shelf. (Auth.)

CHARGED DISLOCATION IN ICE: 1. EXIST-ENCE AND CHARGE DENSITY MEASURE-MENT BY X-RAY TOPOGRAPHY.

Itagaki, K., Nov. 1979, 12p., ADA-078 775, 23 refs. ICE ELECTRICAL PROPERTIES. BLECTRIC

CHARGE, DISLOCATIONS (MATERIALS), X RAY ANALYSIS, ICE CRYSTAL STRUCTURE.

The motion of dislocations in single crystal ice under an electric field was observed by using X-ray topographic methods. Electric charge density on these dislocations was deduced from the amplitude and length of the dislocation segment under the known AC electrical field. In linear charge density, considerable variation is possible, depending on the effective field acting on the dislocation lines.

CR 79-26 LAKE CHAMPLAIN ICE FORMATION AND ICE FREE DATES AND PREDICTIONS FROM METEOROLOGICAL INDICATORS.

Bates, R.E., et al, Nov. 1979, 21p., ADA-079 640, 11 refs.

Brown, M.-L.

34-1745 LAKE ICE, ICE FORMATION, ICE BREAKUP, METEOROLOGICAL DATA, PERIODIC VARIA-

TIONS.

A 19-yr record of the annual closing and opening dates of operation of the Lake Champlain ferry at Grand Isle, Vermont, which are controlled by the lake's ice cover, was made available to CRREL. These navigation records accurately approximated the freeze-over and breakup dates for the ferry crossing area between Gordon Landing, Vermont, and Cumberland Head, New York. When compared statistically with water temperature and climatological data for the same years at nearby Lake Champlain locations, the dates allowed securate predictions of ice formation. From nearby sir temperature records, cumulative freezing degreeday (C) cuives were plotted for each year of record, and ice formation dates and standard deviations were predicted with considerable accuracy. Several methods of predicting ice formation on Lake Champlain were attempted. The most accurate approach used a combination of water temperatures and freezing degree-days. The influence of wind speed on ice cover formation and prediction are also discussed in the report. in the report.

SOME BESSEL FUNCTION IDENTITIES ARIS-ING IN ICE MECHANICS PROBLEMS. Takagi, S., Nov. 1979, 13p., ADA-078 709, 10 refs.

34-1609 ICE MECHANICS, ANALYSIS (MATHEMAT-

ICS).

ICS).

Some Bessel function identities found by solving problems of the deflection of a floating ice plate by two different methods are rigorously proved.

The master formulas from which all the identities are derived are in a Fourier reciprocal relationahip, connecting a Hankel function to an exponential function. Many new formulas can be derived from the master formulas. The analytical method presented here now opens the way to study a hitherto impossible type of problem-the deflection of floating elastic plates of various shapes and boundary conditions.

ELECTRON MICROSCOPE INVESTIGATIONS OF FROZEN AND UNFROZEN BENTONIT Kumai, M., Nov. 1979, 14p., ADA-078 776, 12 refs.

ELECTRON MICROSCOPY, FROZEN GROUND PHYSICS, SOIL STRUCTURE, CLAY SOILS

PHYSICS, SOIL STRUCTURE, CLAY SOILS. Transmission and scanning electron micrographs of Umist bentonite revealed thin, mica-like grains with irregular shapes. Most of the bentonite showed electron diffraction ring patterns, but some showed hexagonal net patterns as well as ring patterns. The lengths of the unit cells were calculated to be 5.18 Å along the a-axis and 8.97 Å along the b-axis. Semiquantitative analyses were made using an energy dispersive spectrometer. Common elements such as Si, Ti, Al, Fe, Mg, Na and K were determined. The molecular ratio of SiO2-Al2O3 was calculated to be 492:100 for the bulk sample, indicating that Umist bentonite is similar in most respects to Wyoming bentonite, and is classified as a montmorillonite. The microstructure of frozen Umist bentonite was observed at a specimen temperature of -100C using a scanning electron

screecepe equipped with a cold stage. Prozen bentonite and gregated ice patterns formed from wet bentonite were exam-sed using an X-ray map and Si X-ray line scan. Sublimation recesses of ice in the frezen bentonite were observed at speci-ten temperatures of -60 and -80C. After sublimation of the se, the bentonith displayed a honeycomb structure. It was nachided that the freezing-sublimation cycle in frozen soil toreasses the normeshifty of water vanor due to the threesees the permeshility of water vapor due to the three-ensional structure of the coagulated clay formed by

ANALYSIS OF PLASTIC SHOCK WAVES IN SNOW.

Brown, 1 34-2528 , R.L., 1979, 14p., ADA-080 051, 12 refs.

WAVE PROPAGATION, SNOW DEFORMA-TION, SHOCK WAVES, LOADS (FORCES), ANALYSIS (MATHEMATICS).

ANALYSIS (MATHEMATICS).

As analytical study of the propagation of shock waves in show was carried out to evaluate the response of medium density snow to high rates of loading. One solution was developed for steady shock waves; this resulted in calculation of pressure jump, density jump and stress wave speed. Correlation with available experimental data was found to be good. Nonsteady shock waves were also considered in order to evaluate wave attenuation rates in snow. Very good. Nonsteady anock waves were also considered in order to evaluate wave attenuation rates in snow. Very few data were available to compare with the analytical results, so no definite conclusions on the part of the study could be made. The results show, however, that shock waves that produce plastic deformation attenuate at extremely high rates and that differences in pressure between two waves are quickly eliminated within a short distance. Calculations were also made to evaluate the effect of wave fromenous were also made to evaluate the effect of wave frequency on attenuation rates. The results show that, for plastic waves, frequency is not a predominant factor for determining attenuation rates. (Auth.)

CIR 79-30 SUPPRESSION OF RIVER ICE BY THERMAL RFFLUENTS.

Ashton, G.D., Dec. 1979, 23p., ADA-080 654, 5 refs. 34-2283

RIVER ICE, ICE CONTROL, THERMAL DIFFU-SION, THERMAL POLLUTION, HEAT TRANS-FER.

FER.
The ice suppression resulting from discharge of warm water into rivers during winter is analyzed with emphasis on two different cases. In Part 1, the case of a thermal effluent fully mixed across the flow section is analyzed to include the effects of unsteadiness in the effluent temperature and the meteorological variations. The location of the ice edge is determined either by O C water temperature criterion or an equilibrium ice melting analysis. The choice of the applicable criterion emerges naturally from the analysis, even though the location of the ice edge may be considerably different when a steady-state analysis is done. In Part 2, the case of a side discharge of heated effluent is analyzed, also in an unsteady manner, and the effects of transverse dispersion are included in the analysis. Comparisons are made in Parts 1 and 2 to limited field data that are available. CR 80-01

IMPROVED ENZYME KINETIC MODEL FOR NITRIFICATION IN SOILS AMENDED WITH AMMONIUM. 1. LITERATURE REVIEW

Leggett, D.C., et al, Jan. 1980, 20p., ADA-082 303, Refs. p.18-20. Iskandar, I.K. 35-2583

35-2585

WASTE TREATMENT, WATER TREATMENT, SOIL CHEMISTRY, SOIL MICROBIOLOGY,

GROWTH.

Previous research indicates that nitrification in pure cultures can be represented by Michaelis-Menten kinetics. However, the effects of temperature and especially pH have not been treated systematically in any of the previous reviews of the subject. The work reported here is an attempt to synthesize reported temperature and pH effects on nitrification and nitrifier growth rates. In addition we attempt to extend the principles of microbial kinetics to soils. Our work indicates that pH effects can be interpreted mechanistically as inhibitions by hydrogen and hydroxyl ions, nitrous acid, and ammonia. These are incorporated into the Michaelis-Menten expressions. It is also our observation that ammonium oxidizers in natural habitats are characterized by lower Michaelis constants than pure cultures. This is significant particularly in terms of their growth and activity in acid soils. Alternatively, we speculate that profiferation of ammonium oxidizers in acid soils is due to spatial heterogeneity of "pH" at the microsite level.

CR 80-02 WINTER THERMAL STRUCTURE, ICE CONDITIONS AND CLIMATE OF LAKE CHAMPLAIN. R.E., Jan. 1980, 26p., ADA-082 304, 7 refs.

33-2383
LAKE ICE, ICE CONDITIONS, THERMAL REGIMS, ICE FORMATION, ICE THERMAL PROPERTIES, WATER TEMPERATURE, METEOROLOGICAL DATA, WINTER, THERMISTORS, STEPAN PROBLEM.

Winter thermal structure and ice conditions in the land-fast ice cover of Lake Champlain were studied in detail for the winters of 1975-76 and 1976-77. The lake was instrumented to a depth of 9.5 m with a string of highly

calibrated thermistors attached to an ice mooring system and connected to a data logger at Shelburne Point, Vermont, during the winter of 1975-76 and at Gordon Landing on Grand lake, Vermont, during 1976-77. This data logger automatically recorded water temperatures from the surface of the lake through snow, ice and water vertical profiles to the bottom of the lake every four hours. Pertinent meteorological parameters are presented for the appropriate messurement sites during the two winter periods, November 775-April 776, and November 776-April 77. Computations were made of freezing degree days for both winters and correlated with ice formation dates. Predictions of ice growth, using the Stefan equation with an empirical coefficient, were correlated with actual ice growth. Documentation was made of the Lake Champlain Transportation Company's first attempt at wintertime navigation by ferry from Gordon Landing, Vermont, to Cumberland Head, New York, in a land fast ice cover during one of the coldest winters of this century.

BITUMENS, BITUMINOUS CONCRETES, PAVE-MENTS, CEMENT ADMIXTURES, TENSILE PROPERTIES, CRACKING (FRACTURING), STRAIN TESTS, THERMAL EFFECTS, VISCOSI-TY, TRAFFICABILITY.

TY, TRAFFICABILITY.

Pavements containing soft asphalt cement have been shown in the past to be less susceptible to low-temperature contraction cracking, but more susceptible to low-temperature contraction cracking, but more susceptible to traffic-load-associated distress in warm weather, than pavements with harder asphalt cements. This research comprised laboratory testing to determine the properties of asphalt-aggregate mixtures containing three grades of saphalt-caggregate mixtures containing thermally induced distress and traffic-associated distress. From the results it is concluded that only the softest asphalt cement tested (AC 2.5) would perform satisfactorily in a cold climatic zone. The moderately soft (AC 3) and moderately hard (AC 20) asphalt cements showed little susceptibility to thermal cracking in a moderate and a warm climatic zone respectively. The AC 2.5 and AC 5 asphalts are not recommended for use in warm climates, however, owing to increased susceptibility to rutting under traffic.

MAXIMUM THICKNESS AND SUBSEQUENT DECAY OF LAKE, RIVER AND FAST SEA ICE IN CANADA AND ALASKA.

Bilello, M.A., Feb. 1980, 160p., ADA-084 488, 57 refa.

ICE COVER THICKNESS, ICE MELTING, ICE DETERIORATION, LAKE ICE, RIVER ICE, SEA ICE, FAST ICE, AIR TEMPERATURE, ICE FORE-CASTING

CASTING.

Weekly measurements of the thickness of lake, river and fast sea ice made over a period of 10 to 15 years at 66 locations in Canada and Alaska are analyzed, and the portion of the data relating to maximum ice thickness and docay (i.e. the decrease in ice thickness) is examined. Ice thickness curves revealed individual patterns of ice decay, and comparisons between locations disclosed major contrasts in the amount of ice accretion and the times of maximum ice and ice learance. Although many factors affect the ice decay process, this study investigates in detail the effect of thawing temperatures. Concurrent measurements of the air temperature at each location made it possible to analyze the relationship between accumulated thawing degree-days (ATDD) and ice cover decay. Other factors affecting ice ablation and breakup, such as snow-ice formation, snow cover depth, solar rediation and wind are also discussed.

WASTEWATER TREATMENT IN COLD RE-GIONS BY OVERLAND FLOW. Martel, C.J., et al, Feb. 1980, 14p., ADA-084 489, 16

Jenkins, T.F., Palazzo, A.J.

34-325 WASTE TREATMENT, WATER TREATMENT, IRRIGATION, COLD WEATHER PERFORMANCE, ENGINEERING, SOIL CHEMISTRY,

Primary effluent, secondary effluent (package extended aeration plant effluent with BOD's often greater than 30 mg/liter) and tapwater were applied to separate sections of a pilot-scale overland flow site in a cold regions environment. The average application rate for each section was 5.0 cm (2.0 mi.) per week. Performance was evaluated for one year, May 1977 to June 1978. Results of this study demonstrated in.) per week. Performance was evaluated for one year, May 1977 to June 1978. Results of this study demonstrated that overland flow can renovate both primary and secondary effluent during spring, summer and fall seasons. However, during winter, runoff water quality from the primary section contained almost no pollutants during its entire operation. Ammonia was the easiest form of nitrogen to remove and nitrate was the most difficult. Rainstorms did not cause a "flushing" effect. However, ammonia and nitrate concentrations in the runoff increased during snowmelt. The forage yield from the primary and secondary sections was almost twice that of a typical New Hampshire hayfield. Westerwater application during winter caused only minor cases of plant injury. Based on these results, a minimum of 30 days of storage is recommended if overland flow is used to treat primary effluent, the number of storage days predicted by EPA-1 computer program appears to be adequate.

ANALYSIS OF THE PERFORMANCE OF A 140-FOOT GREAT LAKES ICEBREAKER: USCGC KATMAI BAY.

Vance, G.P., Feb. 1980, 28p., ADA-084 736, 8 refs.

ICEBREAKERS, BUBBLES, PROTECTIVE COAT-INGS, ICE COVER THICKNESS, ICE FRICTION, ICE STRENGTH.

ICE STRENGTH.
This report presents the results of the tests on the new U.S. Coast Guard 140-ft icebreaker Katmai Bay (WTGB-101) in the level plate ice and brash ice in Whitefish Bay and the St. Marys River. The results indicate that the vessel can penetrate 22 in. of level freshwater ice with in. of brash ice in a continuous mode and at lesst 30 in. of plate ice by backing and ramming. The installed bubblet system decreased the required power of the vessel from 10 to 30% in brash ice and 25 to 35% in level ice. The low friction coating appears to be effective in decreasing the friction factor when it remains intact; when it peels off, it appears to make conditions worse than plain paint. An average dynamic friction factor of 0.15 could be used over the entire hull for these tests.

HIGH-EXPLOSIVE CRATERING IN FROZEN AND UNFROZEN SOILS IN ALASKA

Smith, N., Feb. 1980, 21p., ADA-084 702, 8 refs. 34-3326

FROZEN GROUND MECHANICS, EXPLOSION EFFECTS, SEASONAL FREEZE THAW, TALIKS, EXCAVATION, TESTS.

EXCAVATION, 1831S.

Explosive cratering tests were conducted in seasonally frozen and thawed gravel at Pt. Richardson near Anchorage, Alaska, and in seasonally frozen and thawed silt overlying permafrost and in silt permafrost at Pt. Wainwright near Pairbanks, Alaska. Explosive charge weights ranged from 26 to 3120 lb, and charge burial depths ranged from about 3 to 40 ft. The cube root of the charge weight scaling was used to determine maximum scaled crater dimensions and optimum

scaled depth of burial of the charge. Test results for frozen and thawed gravel were essentially the same because of the low moisture content and the relatively shallow depth of freezing (5 to 6 ft). The optimum depth of burial of the charge for maximizing the apparent radius and depth and the true radius was about 1.8 times the cube root of the charge weight for both the frozen and thawed conditions. In seasonally frozen silt overlying a talk and silt permafrost, the maximum scaled crater dimensions and optimum scaled burial depths of the charge were smaller than for the thawed condition except for the true crater dimensions. The characters of the charge were smaller than for the thawed condition except for the true crater dimensions. condition except for the true crater dimensions. The chan-neling of energy in the tails produces maximum crater dimen-sions and an optimum burial depth for the true crater that is larger than for the thawed condition. The results for the homogeneous silt permatrost were very similar to the frozen gravel results, with much smaller maximum crater dimensions and smaller optimum charge burial depths than for the thawed silt overlying permatrost.

MATHEMATICAL MODEL TO CORRELATE FROST HEAVE OF PAVEMENTS WITH LABORATORY PREDICTIONS.

Berg, R.L., et al, Feb. 1980, 49p., ADA-084 737, 67

MATHEMATICAL MODELS, FROST HEAVE, PROST PENETRATION, HEAT TRANSPER, SOIL WATER MIGRATION, PAVEMENTS, COMPUTERIZED SIMULATION, LABORATORY TECHNIQUES, FORECASTING.

RI IECTINIQUES, FORECASTING.

A mathematical model of coupled heat and moisture flow in soils has been developed. The model includes algorithms for phase change of soil moisture and frost heave and permits several types of boundary and initial conditions. The finite element method of weighted residuals (Galerkin procedure) was chosen to simulate the spatial regime, and the Crank-Nicholson method was used for the time domain portion of the model. To facilitate evaluation of the model, the time were essentially decompled; moisture fluxes were essentially decompled; moisture heat and moisture fluxes were essentially decoupled; moisture flux was then simulated socurately, as were best flux and frost heave in a laboratory test. Comparison of the simulated and experimental data illustrates the importance of unsaturated and experimental data illustrates the importance of unsaturated hydraulic conductivity. It is one parameter which is difficult to measure and for which only a few laboratory test results are available. Therefore, unsaturated hydraulic conductivities calculated in the computer model may be a significant source of error in calculations of frost heave. The algorithm is the contractive of the contractive and overharden was incompared to the contractive and the cont source of error in calculations of frost heave. The algorithm incorporating effects of surcharge and overburden was inconclusively evaluated. Time-dependent frost penetration and frost heave in laboratory specimens were closely simulated with the model. After 10 days of simulation, the computed frost heave was about 2.3 cm vs 2.0 cm and 2.8 cm in two tests. Frost penetration was computed as 15 cm and was measured at 12.0 cm and 12.2 cm in the two laboratory samples after 10 days.

ROOF LEAKS IN COLD REGIONS: SCHOOL AT

CHEVAK, ALASKA.
Tobiasson, W., et al, Apr. 1980, 12p., ADA-084 914.

34-3327

ROOFS, LEAKAGE, BUILDINGS, MELTWATER, SNOW ACCUMULATION, CONDENSATION, SUBPOLAR REGIONS.

SUBPOLAR REGIONS.
Four types of roof leaks occurred at a new school building in Chevak, Alsaka: 1) blowing snow entered the roof through eave vents and then melted, 2) stush and ice in roof valleys caused meitwater to overflow the valley flashing and run into the building, 3) water entered at a roof wall intersection and 4) in many areas water entered through gaps in the sloping plywood deck. Sealing the eave vents made it impossible for blowing snow to enter the roof at the eaves. Electric heat tapes eliminated the valley icing problems. Missing flashing was responsible for the roof-wall intersection leaks. The absence of a vapor barrier in the roof was the cause of many leaks. It was recommended that the roof be repaired from the exterior by removing component elements down to the plywood deck, installing an adhered continuous vapor barrier and reassembling the roof. An alternative roof cladding of composition shingles was discussed as was conversion to a "cold roof." The roof was repaired and modified following recommendations, and problems appear to have been solved.

CR 80-12 SIMPLIFIED MODEL FOR PREDICTION OF NITROGEN BEHAVIOR IN LAND TREAT-MENT OF WASTEWATER.

Selim, H.M., et al, Apr. 1980, 49p., ADA-085 191, 23 refs.

Iskandar, I.K. 34-3263

WASTE TREATMENT, WATER TREATMENT, NUTRIENT CYCLE, SOIL CHEMISTRY.

NOIRIENT CYCLE, SOIL CHEMISTRY.

A simplified model for simulation of nitrogen transformations and transportation in land treatment of wastewater is presented. The purpose of the model is to predict the behavior of NH4-N and NO3-N in the soil profile in land treatment systems. The program is based on the solution of the transfert soil water flow equation simultaneously with the equations describing the transformation, transport, and plant uptake of nitrogen in the soil. The program is valid

for uniform as well as multilayered soil profiles and can be adapted to incorporate various nitrogen transformation mechanisms and boundary conditions. The model can be used as a tool to predict the fate of nitrogen in land treatment systems. Model sensitivity to changes in the rate of nitrification, ammonium ion exchange, and rate of plant uptake of nitrogen is also described. Description of the computer program, the program listing, and an example of input data are presented.

CR 80-13 FRACTURE BEHAVIOR OF ICE IN CHARPY IMPACT TESTING. Itagaki, K., et al, June 1980, 13p., ADA-089 920, 17

35-973

ICE CRACKS, FRACTURING, IMPACT TESTS, TEMPERATURE EFFECTS, DOPED ICE, ICE COMPOSITION, ICE CRYSTAL STRUCTURE.

COMPOSITION, ICE CRYSTAL STRUCTURE. Specimens prepared from various types of ice without introducing excessive defects were tested at temperatures ranging from -2 to -190C. These tests indicated slightly higher Charpy values at lower temperatures and in more highly dispersed material concentrations. Three modes of fracture occurred during testing. Depending on the temperature and the material composition, either of the first two modes of macure, will appear and will show a normal frequency distribution of Charpy values in each type of ice. The third mode, fracture from both ends, which frequently occurred in the (NH4F) doped ice, gave Charpy values two to five times higher than the mean value for normal fracture. It can, therefore, be concluded that certain types of doping can alter the mode of fracture, through which drastic modifications of impact resistance may be possible.

GEOBOTANICAL ATLAS OF THE PRUDHOE BAY REGION, ALASKA.

PRUDHOE BAY.

This atlas illustrates the interrelationships among the landforms, solls and vegetation of a portion of the Arctic Coastal
Pisin of Alsaka. The Prudhoe Bay region is dominated
by an alkaline peaty coastal tundra, a type that has not
been intensively studied. Porty-two vegetation communities, thirteen major landforms, and eight soil types are described. Several of the plant communities and one soil,
the Pergelic Cryoboroll, have not been described previously.
The vegetation is discussed with respect to three important
predicts temperature, soil pH and soil moisture. Other
aspects of the Prudhoe Bay environment, including geology,
permsfrost, and winter and tammer climate, are discussed
and illustrated. Also included are historical descriptions
of the development of the oilfield and of selected scientific
investigations in the Alsakan Arctic. Master maps present
the landforms, soils and vegetation of a 145-sq km portion
of the oilfield road network at a scale of 1:12,000. Derived
geobotanical special purpose maps, useful for land-use planning
and management of the coopystem, are explained and several
examples are shown for a 3.6 sq km portion of the oilfield.

CR 80-15 TIME CONSTRAINTS ON MEASURING BUILDING R-VALUES. Flanders, S.N., June 1980, 30p., ADA-089 712, 18

55-1998
COLD WEATHER CONSTRUCTION, CONSTRUCTION MATERIALS, THERMAL PROPERTIES, THERMAL CONDUCTIVITY, BUILDINGS, HEAT FLUX, TIME FACTOR, COMPUTER APTICATIONS ANALYSIS MATHEMATICS).

PLICATIONS, ANALYSIS (MATHEMATICS).

PLICATIONS, ANALYSIS (MATHEMATICS). This report discusses the time constraints on measuring the thermal resistance (R-value) of building components. Temperature changes on either side of a building component neutrum neasurement accuracy. Long measurement times and measurement times corresponding to a consistent diurnal cycle can be satisfactory; however, individual temperature changes cause significant error for shorter measurement periods. This report shows how to scale the thermal properties of individual constituent materials in a building element to determine its characteristic thermal time constant. The report then demonstrates the size of measurement error resulting from a variety of changes in temperature with representative walls of different time constants.

MORPHOLOGY AND DISTRIBUTION OF THE ACANTHOECIDAE (CHOANOFLAGELLATA)
FROM THE WEDDELL SEA DURING THE AUS-

TRAL SUMMER, 1977.
Buck, K.R., July 1980, 26p., ADA-090 680, 35 refs. 35-1721

PLANKTON, MARINE BIOLOGY, SEA ICE DISTRIBUTION, OCEAN ENVIRONMENTS, ICE EDGE, CRYOBIOLOGY, ANTARCTICA—WED-

DELL SEA.

Eight species of foricate choanoflagellates (Acanthoecidae) were observed in samples obtained from the Weddell Sea during the austral summer, 1977. Habitats in which choanoflagellates were found included the water column, the edges of ice floes, ponds on ice floes, and the interiors of ice floes. The presence of choanoflagellates within the ice floes. The presence of choanoflagellates within the ice floes are the season of the community, the ice algae and the bacteria. The presence in the ice of seven species with both a caudal appendage and anterior projections suggests a positive relationship between this lorica configuration and the ice habitat. Mechanisms of variance of transverse costal diameters between genera may be useful to the taxonomy and phylogeny of this family. may be useful to the taxonomy and phylogeny of this family. COLD WEATHER CONSTRUCTION, PIPE-LINES, SNOW ROADS, PERMAFROST PRESER-VATION, SNOW STRENGTH, SOIL TRAFFICA-BILITY, ENVIRONMENTAL PROTECTION, AR-TIFICIAL SNOW.

TIFICIAL SNOW.

Construction pads made of snow were used to build two sections of the Trans Alaska Pipeline and a small gas pipeline during the winter of 1975-76. Construction during the winter of 1975-76. Construction during the winter has become increasingly common in the Arctic. Surface travel and the use of heavy construction equipment on the unprotected tundra have been severely restricted, even during the winter, so the use of temporary winter roads and construction pads built of snow and ice has been advocated and is being adopted. The three snow construction pads mentioned above were the first snow roads and construction pads have two objectives: to protect the underlying vegetation and upper layers of the ground, and to provide a hard, smooth surface for travel and the operation of equipment. Several types have been built, and a brief discussion is given of their history and classification of the Trans Alaska Pipeline and the small gas pipeline in 1975-76 were visited and observed while in use.

HEAT AND MASS TRANSFER FROM FREELY FALLING DROPS AT LOW TEMPERATURES. Zarling, J.P., Aug. 1980, 14p., ADA-090 522, 18 refs. 35-594

DROPS (LIQUIDS), FREEZING, HEAT TRANSFER, MASS TRANSFER, LOW TEMPERATURE TESTS, SUPERCOOLING, ICE PHYSICS, COM-APPLICATIONS, CONSTRUCTION MATERIALS.

MATERIALS.

The use of ice as structural material is common practice for certain applications in cold regions. Techniques such as surface flooding or water spraying are used to accelerate ice growth rates, thereby lengthening the winter construction season. This report examines the heat and mass transfer rates from freely falling water drops in cold air. Design equations which predict the amount of supercooling of the drops as a function of outdoor ambient temperature, drop size and distance of fall are given.

ENVIRONMENTAL ENGINEERING AND ECO-LOGICAL BASELINE INVESTIGATIONS ALONG THE YUKON RIVER-PRUDHOE BAY HAUL ROAD.

Brown, J., ed, Sep. 1980, 187p., ADA-094 497, Refs. p.151-155. For individual chapters see 35-1769 through 35-1772.

TAL IMPACT, ENGINEBRING, ECOLOGY.

During the period 1975-1978 the Federal Highway Administration aponsored a series of environmental engineering investigations along the Yukon River to Prudhoe Bay Haul Road.
In 1976 the Department of Benergy joined these investigations
with a series of ecological projects which continue to the
prosent. Both agencies' research efforts were conducted
on a cooperative basis with CRREL's in-house research program. The objectives of the research focused on 1) an

evaluation of the performance of the road, 2) an assessment of changes in the servironment associated with the road, 3) documentation of flore and vegetation along the 577-km-long transact, 4) methodologies for revegetation and restoration, and 5) an assessment of biological parameters as indicators of servironmental integrity. In support of these objectives, specific studies were undertaken that investigated the climate along the road, thaw and subsidence beneath and adjacent to the road, drainage and side slope performance, distribution and properties of road dust, vegetation distribution, vegetation distribution and restoration, and construction of the fuel gas line. This report presents background information on the region, detailed results of the road thaw subsidence and dust investigations, and summaries of revegetation, fuel gas line, vegetation distribution, soil, and weed studies.

INVESTIGATIONS OF SEA ICE ANISOTROPY. ELECTROMAGNETIC PROPERTIES, STRENGTH, AND UNDER-ICE CURRENT ORIENTATION. Kovacs, A., et al, Sep. 1980, 18p., ADA-092 089, 16

reft.

Morey, R.M. 35-1891 SEA ICE, ANISOTROPY, ICE STRENGTH, ELEC-TROMAGNETIC PROPERTIES, ICE CRYSTAL STRUCTURE, BRINES, OCEAN CURRENTS, RADIO ECHO SOUNDINGS.

RADIO BCHO SOUNDINGS.
Results of impulse radar studies of sea ice give support to the concept of a sea ice model in which the ice bottom is composed of an array of lossy parallel plate waveguides. The fundamental relation between the average bulk brine volume of sea ice and its electrical and strength properties is discussed as is the remote detection of under-ice current alignment. It was found that 1) the average effective bulk dielectric constant is dependent upon the average bulk brine volume of the sea ice; 2) sea ice anisotropy, arising from a bottom structure of crystal platelets with a preferred caxis horizontal alignment, can be detected by radio echo counding measurements made not only on the ice surface but also from an airborne platform; 3) the effective coefficient of reflection from the sea ice bottom decreases with increasing bulk brine volume, and is typically one to two orders of magnitude lower than the coefficient of reflection from the ice surface; and 4) the loases in sea ice increase with increasing average bulk brine volume.

MECHANICS OF CUTTING AND BORING. PART 5: DYNAMICS AND ENERGETICS OF INDENTATION TOOLS.

Mellor, M., Sep. 1980, 82p., ADA-092 365, 40 refs.

DRILLING, ICE CUTTING, EXCAVATION, PER-MAFROST, ROCK DRILLING, LOADS (FORCES), EQUIPMENT, DYNAMIC LOADS, STRESSES, DESIGN.

STRESSES, DESIGN.

This report deals with the cutting of rock and other brittle materials by means of indentation tools. The principles of indentation cutters are dealt with at length, the coverage including elastic contact stresses for initial locating by various types of indenters, application of formal plasticity theory penetration analyses, and a variety of theories and penetration analyses that are not based on plasticity theory. Practical indentation mechanisms are described, and theoretical analyses are given for the dynamics and energetics of various types of roller cutters.

The final section reviews experimental investigations and results for rock-cutting discs, giving a systematic summary of available data.

CR 80-22 NEUMANN SOLUTION APPLIED TO SOIL SYSTEMS.

Lunardini, V.J., Oct. 1980, 7p., ADA-092 244, 12 refs.

Solic Freezing, Ground Thawing, Freeze Thaw Tests, Thermal Conductivity, Thermal Diffusion, Active Layer, Phase Transformations, Time Factor, Analysis (Mathematics).

TOR, ANALYSIS (MATHEMATICS).

The only complete, analytic solution for conduction problems with phase change is the Neumann solution. The Neumann solution is valid for phase change in a semi-infinite, homogeneous medium with a step change in aurhoc temperature, starting from an initial temperature which can be different than or equal to the fusion temperature of the medium. The Neumann solution, when applied to soils, forms the basis of a number of formulae for calculating the depths of freezing or thawing. Widely used graphs were previously developed that are valid only when the ratios of the thermal officiality idea of the frozen and thawed soil are unity. In this report general charts, applicable to any property ratios, are developed. The figures have been drawn specifically for soil systems, but they are applicable to any material with appropriate property ratios.

CR 80-23 MODELING OF ANISOTROPIC ELECTRO-MAGNETIC REFLECTION FROM SEA ICE. Golden, K.M., et al, Oct. 1980, 15p., ADA-094 620, 21 refs

BCHOES.

The contribution of brine layers to observed reflective anisotropy of sea ice at 100 MHz is quantitatively assessed. The sea ice is considered to be a stratified, inhomogeneous, anisotropic dielectric consisting of pure ice containing ordered arrays of conducting inclusions (brine layers). Below the transition zone, the ice is assumed to have constant azimuthal eaxis orientation within the horizontal plane, so that the orientation of brine layers is uniform. The brine layers are also assumed to become increasingly well-defined with depth, since adjacent brine inclusions tend to fuse together with increasing temperature. A theoretical explanation for observed reflective anisotropy is proposed in terms of anisotropic electric flux penetration into the brine layers. Penetration anisotropy and brine layers constant, see the constant of sea ice. In order to illustrate the above effects we present a numerical method of approximating the reflected power of a plane wave pulse incident on a slab of sea ice. Mixture dielectric constant, calculated for two polarizations of the incident wave, are used to calculate power reflection coefficients for the two polarizations.

35-1723 ICE MECHANICS, SHEAR STRESS, HYDRAU-LICS, SUBGLACIAL OBSERVATIONS, SUR-FACE ROUGHNESS, WATER, VELOCITY, EX-PERIMENTATION, MODELS.

PERIMENTATION, MODELS.

The fluid shear stress applied to the underside of a simulated floating ice cover was measured in a laboratory flume. The measured values were compared with values of the ahear stress computed from the von Karman-Frandtl velocity distribution fitted to the velocity profiles measured beneath the cover. For the lower velocity runs (about 0.079 m/s) the measured and computed values of the ahear stress were in close agreement. At the high velocity flows (about 0.138 m/s) the measured values were roughly one-half those calculated from the velocity distribution. As the underside of the cover became increasingly rougher, the position of maximum velocity moved closer to the bottom of the channel. It was shown that the Darry friction coefficient is exponentially related to a normalized ice cover thickness, which suggests that it is measure of the roughness of a fragmented ice cover.

SINGLE AND DOUBLE REACTION BEAM LOAD CELLS FOR MEASURING ICE FORCES. Johnson, P.R., et al, Oct. 1980, 17p., 15 refs.

Zarling, J.P.
35-1724
ICE LOADS, RIVER ICE, BRIDGES, MEASUR-ING INSTRUMENTS, LOADS (FORCES).

ING INSTRUMENTS, LOADS (FORCES).

Two new types of load cells for attachment to bridge piers and direct measurement of ice forces were developed and tested with one type being installed on a pier of the Yukon River Bridge northwest of Pairbank, Alsaka. Both types of load cells used beams supported by base plates and carried nose plates that were loaded by the ice. The loads were imposed at the beams at locations differing from the support reactions so that the loads developed moments in the beams. By instrumenting them with strain gauges, the loads could be measured. Detrils of the design of the load cells, the measured of calculating the loads and experience obtained with load cells are discussed.

BLOCK MOTION FROM DETONATIONS OF BURIED NEAR-SURFACE EXPLOSIVE AR-

ROCK MECHANICS, EXPLOSION EFFECTS, EXPLOSIVES, SUBSURFACE STRUCTURES, SOIL MECHANICS.

SOIL MECHANICS.

A vital concern to the survivability of hardened underground structures in rock is the relative displacement induced along geologic discontinuities by nearby explosions. Such displacement, commonly termed block motion, can occur along faults, joints, bedding planes and other structural weaknesses in rock. This report documents all occurrences of block motion observed during the development of DIHEST, a series of shallow-buried high explosive experiments designed to simulate the direct induced ground motions from a nuclear surface burst. Instances of block motion are described,

along with pertinent details of the explosive arrays, geology and ground motion fields. The influence of these and other factors on the direction and magnitude of block motion is discussed.

PHASE CHANGE AROUND A CIRCULAR PIPE Lunardini, V.J., Dec. 1980, 18p., ADA-094 600, 12

ron.

PIPES (TUBES), HEAT TRANSFER, PERMA-FROST THERMAL PROPERTIES, STEFAN PROBLEM, PHASE TRANSFORMATIONS, FROZEN GROUND STRENGTH, THERMAL DIFFUSION, FREEZE THAW CYCLES, ANAL-YSIS (MATHEMATICS).

YSIS (MATHEMATICS).

No general, analytical solution exists for phase change around a cylinder, thus, approximate methods have been evaluated. The heat balance integral technique applied to the cylinder gave excellent results when compared to published numerical solutions. Graphical solutions are given for phase change about a cylinder for ranges of the Stefan number, superheat parameter, and property value ratios for typical soils. An approximate, general solution has been derived which is ressonably accurate and can be used for any values of the above-mentioned parameters. The effective thermal difficulties that have shown to be useful for practical above-mentioned parameters. The effective thermal fusivity method has been shown to be useful for prac-problems of phase change.

CR 80-28 CLEARING ICE-CLOGGED SHIPPING CHAN-NELS.

Vance, G.P., Dec. 1980, 13p., ADA-095 490, 18 refs. 35,2000

CHANNELS (WATERWAYS), ICE REMOVAL, ICE NAVIGATION, ICE CONDITIONS, RIVER ICE, STREAM FLOW, WATER LEVEL.

ICE, STREAM FLOW, WATER LEVEL.

This report investigates the feasibility of clearing ice from
the shipping channel of the St. Marys River. Four basic
concepts are investigated: disposal under the ice, disposal
on top of the ice, sturying and rathing. Each technique
was found to have application in limited portions of the
river with the exception of disposal on top of the adjacent
ice sheet, which is deemed feasible throughout the river
system. Disposal onto the adjacent ice sheet will increase
the free stream velocity less than 1.0 ft/s (30.5 cm/s) and
raise the water level less than 1.0 ft (0.30 m). Further
model and field tests are recommended to validate the findings
of this report. of this report.

OIL SPILLS, PERMAFROST, VEGETATION, DAMAGE, SOIL MICROBIOLOGY, THAW DEPTH, SLOPES, FREEZE THAW CYCLES.

DAMAGE, SOIL MICROBIOLOGY, THAW DEPTH, SLOPES, FREEZE THAW CYCLES. This study was conducted to determine the short- and long-term physical, chemical and biological effects of spills of not Prudhoe Bay crude oil on permaftrest terrain near Pairbanks, Alaska. Two experimental oil spills, one in winter and one in summer, of 7570 liters (2000 gallons) were made at a forest site. The winter-spill oil moved within the surface moss layer beneath the snow. The summer-spill oil moved primarily below the moss in the organic soil. The oil moved faster and further downslope in the summer spill. Oil in the winter spill stopped during the first day but remobilized and flowed further downslope in the spring. The total area affected by the summer spill spill. The initial heat of the spilled oil had little measurable thermal effect on the soil. However, thaw depth significantly increased following two full thaw seasons. The greatest increases occurred beneath oil black-ened surfaces. Exporation of volstile components is the most significant weathering process in the first two years. Volatiles evaporated faster from surface oil than from oil carried deeper into the soil profile. Microbial degradation has not been observed. The indigenous soil microbial populations responded differently to winter and summer oil applications, ranging from inhibition to stimulation, with stimulation appearing to predominate. Vegetation showed both immediate and long-term damage. Denage was greatest near the top of the slope and in areas with surface oil. CTP 86.36

FIELD COOLING RATES OF ASPHALT CON-CRETE OVERLAYS AT LOW TEMPERATURES. saton, R.A., et al, Dec. 1980, 11p., ADA-095 489, 7 nefs.

Berg, R.L. 35-2002

TEMPERATURE EFFECTS, BITUMINOUS CON-CRETES, COOLING RATE, LOW TEMPERA-TURE TESTS, ROADS, PAVEMENTS, COMPAC-TION.

Six overlay test sections were placed on an existing to road in Hanover, New Hampshire, to gain experience

compaction of asphalt pavements at rolling temperatures as low as 150 F. The asphalt cement and aggregate used had mix characteristics similar to those of the mix expected to be used for a proposed overlay project at Thule Air Bass, Greenland. Results of the overlay tests showed that computer-modeled cooling curves can be accurate predictors of the actual asphalt overlay cooling with time. In Addition, the effects of temperature upon compaction were determined and it was found that nuclear gauges, when used and calibrated properly, successfully monitored mix density changes during compaction.

ICING ON STRUCTURES.

Minsk, L.D., Dec. 1980, 18p., ADA-095 474, 34 refs.

STRUCTURES, ICING, ICE ACCRETION, ICE LOADS, ICE PREVENTION, HUMIDITY, WIND PRESSURE, ICE COVER THICKNESS.

PRESSURE, ICE COVER THICKNESS.

Ice accretion on structures built on the earth's surface is discussed. Sources of water are the atmosphere or water bodies near or surrounding the structure. Ice types include frost, rime, giaze and spray; properties and conditions governing their formation are presented. Methods of estimating accretion rates and total accretion on structures are given, and canadian codes for ice and wind loads on structures are included. Techniques for preventing ice accretion or removing accreted ice are presented.

CR 81-01 ANALYSIS OF ICE JAMS AND THEIR METEOROLOGICAL INDICATORS FOR THREE WINTERS ON THE OTTAUQUECHEE RIVER, VERMONT.

Bates, R.B., et al, Feb. 1981, 27p., ADA-099 173, 11 refa.

35-3926

ICE JAMS, ICE BREAKUP, ICE FORMATION, RIVER ICE, METEOROLOGICAL DATA.

RIVER ICE, METEOROLOGICAL DATA.

The formation of ice jams and their meteorological indicators were studied in detail for the winters of 1975-76, 1976-77 and 1977-78 on the Ottauquechee River at and east of Woodstock, Vermont. Meteorological data are presented for nearby National Weather Service Co-Operative Stations as well as for CRREL sites on the Ottauquechee River. The severity of each winter is discussed, as are the effects of a heavy rainfall on a high water-equivalent snow cover. The resultant runoff and subsequent ice jamming that occurs is discussed. Continuous monitoring of water temperature before, during and immediately after an ice cover formed on the river during the winter of 1977-78 is included. The report includes a section on warm sewer outfall effects on on one river ouring the winter of 1977-78 is included. The report includes a section on warm sewer outfall effects on the ice at and below a municipal treatment plant. Retrieved data will assist in future modeling studies to help predict ice formation, growth, decay and jamming of river ice covers.

CR 81-02 HYPERBOLIC REFLECTIONS ON BEAUFORT SEA SEISMIC RECORDS. Neave, K.G., et al, Mar. 1981, 16p., ADA-099 172, 8

Selimann, P.V., Delaney, A.J.

36-318

BOTTOM SEDIMENT, SEISMIC REFLECTION, OCEAN BOTTOM, ICE CONDITIONS, SEA ICE, BEAUFORT SEA.

Many hyperbolic reflect ons have been observed on marine Many hyperbolic reflections have been observed on marine seismic records obtained during oil exploration in the Beaufort Sea, and on USGS seismic sub-bottom profiles from the Prudhoe Bay vicinity. A hyperbolic projection system was designed to rapidly measure seismic velocities from the curves on the records. The velocities observed were approximately the velocity of sound in water. The hyperbolic signals also showed dispersion properties similar to acoustic normal modes in shallow water. These observations indicate that the strength rememble for the hyperbolic signals are similar to acoustic normal modes in shallow water. These observations indicate that the strength rememble for the hyperbolic signals are similar to acoustic normal modes in shallow water. normal modes in shallow water. These observations indicate that the signals responsible for the hyperbolic reflections propagate as normal modes within the layer, with very limited penetration of the seabed. Determinations of the dominant frequency of these signals indicate that the penetration into the seabed has a characteristic attenuation depth (akin depth) of about 1.5 m for the sub-bottom profiles and 12 m for the marine records. It therefore appears that some hyperbolic reflections may be generated by variations in material that occur near the seabed. There is some evidence of linearity of the anomalies, possibly related to sediment-filled or open ice gouges, or other changes in material properties at shallow depths.

HYDRAULIC MODEL STUDY OF A WATER IN-TAKE UNDER FRAZIL ICE CONDITIONS. Tantillo, T.J., Mar. 1981, 11p., ADA-099 171, 8 refs. 36-319

36-319
WATER INTAKES, ICE CONDITIONS, FRAZIL ICE, HYDRAULIC STRUCTURES, ICE PREVENTION, PROTECTION, MODELS, BUOYANCY.
A 1:24 scale hydraulic model study of a water intake under frazil ice conditions is presented. The intake, located 9 m below the surface of the St. Lawrence River in Massena, New York, has a throughflow of 0.14 cu m/s. The model study, conducted in the refrigerated flume facility of the U.S. Army Cold Regions Research and Engineering Laboratory, investigated methods of minimizing the frazil ice blockage on the intake. Two protective structures were modeled

and the relative benefits of each are presented. The additional cross-sectional area provided by the protective structures lowered the vertical velocity component of the intake water to 0.0027 m/s. At this velocity the buoyant force acting on the frazil ice particle is larger than the downward drag force, causing the particle particle to rise. The results demonstrate that under certain low flow conditions a protective structure can minimize frazil ice blockage problems.

CR 81-04 MOVEMENT STUDY OF THE TRANS-ALASKA PIPELINE AT SELECTED SITES. Ueda, H.T., et al, Apr. 1981, 32p., ADA-101 605, 3

Garfield, D.B., Haynes, F.D.

PIPELINES, MECHANICAL PROPERTIES, STA-BILITY, PIPELINE SUPPORTS, ANCHORS, UNITED STATES—ALASKA.

UNITED STATES—ALASKA.

Eight sites along the trans-Alaska pipeline from the Denail Fault to Pairbanks were selected for pipeline and pipeline support movement studies. Four measurement surveys were conducted, starting before all pumping operations began up to September 2, 1978, to determine the lateral and longitudinal pipe movement due to the thermal expansion of elevated actions of the pipeline, the tilt of the vertical support members (VSM's), and the changes in relative elevation of the support crossbeams. A maximum lateral and longitudinal motion of the pipe of 13 3/4 in and 2 3/16 in respectively were measured up to September 1978. Tilt data for 180 VSM's showed little change over a one-year period, with only 5 VSM's tilting more than 0.5 deg. Relative elevation measured over a one-year period. Comparisons of our data with a-built elevations at 8 sites shows a few large differences that cannot be readily explained. In general the pipeline and its supports, at least at the sites studied, show minimal movement and activity. that cannon and its supports, at least and activity.

CR 81-05 VIBRATIONS CAUSED BY SHIP TRAFFIC ON AN ICE-COVERED WATERWAY. Haynes, F.D., et al, Apr. 1981, 27p., ADA-101 541, 11

Maattanen, M.

36-321 SHIPS, VIBRATION, ICE BREAKING, ICE COV-ER, FROZEN GROUND, SEISMOLOGY.

SRILTS, VIBRATION, ICE BREAKING, ICE COVER, FROZEN GROUND, SEISMOLOGY.

Vibrations have been felt on shore along the St. Marys
River in Michigan during the passage of ships through ice.

vibration measurements were made on a ship, on the ice,
on the shore, and on buildings along the shore. Vibration
levels in 1979 were shout an order of magnitude lower
than levels that would cause damage to building walls. Two
factors, however, could have reduced the vibration levels
in 1979: a lack of ice jams and a record high snow cover
which prevented the soil from freezing. Vibration levels
with an ice cover are about four times those without an
ice cover. Icebreaking and opening the channel can reduce
vibration levels by about 50% for a ship following closely
behind another ship. The dominant frequencies measured
on shore were associated with propeller excitation. The
dominant frequencies and magnitude higher than those
on the shore and are related to icebreaking by the bow.
Vibration magnitudes are dependent upon the velocity of
the ship, the energy expended by the ship, the cross-sectional
area of the ship, weather, conditions of the ice and soil,
and site-specific conditions. Further studies are needed
to determine the effects of these factors and to determine
the mode of energy transmission.

ANALYSIS (MATHEMATICS).

A procedure is described for monitoring the microfracturing activity in ice plates subjected to constant loads. Sample time records of freshwater ice plate deflections as well as corresponding total acoustic emission activities are presented. The linear elastic, as well as viscoelastic, response for a simply supported rectangular ice plate is given. Suggested future work using te above procedure is discussed.

HYDRAULIC CHARACTERISTICS OF THE DEER CREEK LAKE LAND TREATMENT SITE DURING WASTEWATER APPLICATION. Abele, G., et al, Apr. 1981, 37p., 3 refs. McKim, H.L., Caswell, D.M., Brockett, B.E.

36-390

SOIL WATER, WASTE DISPOSAL, WATER TREATMENT, HYDRAULICS, DRAINAGE, IR-RIGATION, SEEPAGE, LAND RECLAMATION. During the summer of 1979, wastewater was applied 10 times to the Deer Creek Lake, Ohio land treatment site. Wastewater distribution on the ground during spray application is not uniform: some locations receive less than 70% and

others more than 130% of the mean amount applied. The saturated infiltration rate ranges from moderately slow (0.6 cm/hr after 1 hr) to slow (0.3 cm/hr after 12 hours). The under-drain flow rate increases approximately as the cube of time until 1 hour after the end of application and then decreases as the reciprocal of time squared. The rate and amount of drainage increases with an increase in the initial soil water content and can be predicted from soil tension measurements. It was possible to calculate the mass water budget at the end of a typical application to within \$8% of the actual water applied.

CD 21.02 SEASONAL GROWTH AND UPTAKE OF NU-TRIENTS BY ORCHARDGRASS IRRIGATED WITH WASTEWATER.

Palazzo, A.J., et al, May 1981, 19p., ADA-101 613, 33

refs. Graham, J.M.

GRASSES, NUTRIENT CYCLE, GROWTH, WASTE DISPOSAL, WATER TREATMENT, IRRIGATION, LAND RECLAMATION, SEASON-GRASSES. AL VARIATIONS.

AL VARIATIONS.

A 2-year field study determined the seasonal growth and nutrient accumulation of a forage grass receiving 7.5 cm/wk of primary treated domestic wastewater. The average N and P concentrations in the wastewater were 31.5 and 6.1 mg/l respectively. An established sward of Penniste orchardgrass (Dactytis glomerata L.) was managed on an annual three cutting system. Grass samples were periodically taken to determine plant dry matter accumulation and uptake of N, P and K. Changes in nutrient uptake within a harvest neriod were related to both changes in dry matter taken to determine plant dry matter accumulation and uptake of N, P and K. Changes in nutrient uptake within a harvest period were related to both changes in dry matter accumulation and plant nutrient concentration. For marinum yields and nutrient removal, it is recommended that orchardgrass be initially harvested at the early heading stage of growth in the spring. Subsequent harvests abould be performed at 5- to 6-week intervals. Average daily dry matter, N and P accumulation was greatest during the first harvest period (May in Hanover, N.H.). This would be the most appropriate time to increase the application rate, thus treating excess wasterwater stored during the writer. use most appropriate time to increase the application rate, thus treating excess wastewater stored during the winter. Estimates of monthly plant removal for N and P are presented as a guide in designing land treatment systems according to the procedures given in the EPA/Corps Land Treatment Design Manual.

CR 81-09 ON THE BUCKLING FORCE OF FLOATING ICE PLATES.

Kerr, A.D., June 1981, 7p., ADA-103 733, 12 refs. 36-392

ICE LOADS, PLATES, FLOATING ICE, ICE COVER STRENGTH, DYNAMIC LOADS, COVER STRENGTH, DY MATHEMATICAL MODELS.

MATHEMATICAL MODELS.
The calculation of the largest horizontal force a relatively thin floating ice plate may eart on a structure requires the knowledge of the buckling load for this floating plate. In the published literature on the stability of continuously supported beams and plates, it is usually assumed that this buckling force corresponds to the lowest bifurcation force p(cr). However, recent studies indicate that, generally, this is not the case, and this report clarifies the situation for floating ice plates. This problem is first studied on a simple model that exhibits the buckling mechanism of a floating ice plate but is amenable to an exact nonlinear analysis. This study shows that, depending on the ratio of the rigidities of the "liquid" and "plate", the post-buckling branch may rise or drop away from the bifurcation point. CR 81-10

CR 81-10 REVIEW OF THERMAL PROPERTIES OF SNOW, ICE AND SEA ICE. Yen, Y.-C., June 1981, 27p., ADA-103 734, Refs.

p.25-27. 36-393

ICE THERMAL PROPERTIES, SEA ICE, SNOW DENSITY, SNOW THERMAL PROPERTIES, ICE DENSITY, THERMAL PROPERTIES, COMPRESSIVE PROPERTIES, TERMAL EXPANSION.

SIVE PROPERTIES, TERMAL EXPANSION.
This treatise thoroughly reviews the subjects of density, thermal expansion and compressibility of ice; snow density change attributed to destructive, constructive and melt metamorphism; and the physics of regelation and the effects on penetration rate of both the thermal properties of the wire and stress level. Heat capacity, latent heat of fusion and thermal conductivity of ice and snow over a wide range of temperatures were analyzed with regression techniques. In the case of snow, the effect of density was also evaluated. The contribution of vapor diffusion to heat transfer through snow under both natural and forced convective conditions was excessed.

Expressions representing specific and latent heat of sea ice in terms of sea ice salinity and temperature. Theoretical models were given that can predict the thermal conductivities of fresh bubbly ice and sea ice in terms of salinity, temperature and fractional air content.

REVEGETATION AND SELECTED TERRAIN DISTURBANCES ALONG THE TRANS-ALASKA PIPELINE, 1975-1978.

Johnson, A.J., June 1981, 115p., ADA-138 426, 41

38-4413

REVEGETATION, SOIL EROSION, GRASSES, PIPELINES, ENVIRONMENTAL POLAR REGIONS.

POLAR REGIONS.

Revegetation techniques along the trans-Alaska pipeline as employed by Alyeska Pipeline Service Company during the 1973-1978 summers were observed. Objectives included determining the success of treatments, identifying problems areas, and noticing long-term implications. Observations and photographs at 60 sites located along the trans-Alaska pipeline indicated frequent occurrence of successful revegetation as well as frequent problems, such as erosion, alope instability, poor scheduling of seed application, occurrence of weed species, failure to optimally reuse topsoil and finegrained soil, and low rates of native species reinvasion. Alyeska's visual impact engineering was observed to be very successful, as shown by high first-season survival. However, a related program for establishing willow cuttings was unsuccessful in 1977 but appeared very promising in 1978 largely due to improved management and more favorable growing conditions. Terrain disturbances due to the construction of the fuel gas line, snowpads, and oil spills were examined to identify and describe related environmental impacts on natural vegetation. Proper construction and use of snowpads minimized the extent and severity of disturbance. Crude oil spills, although damaging to vegetation, did not cause total kill of vegetation, and certain types of spills may have only short-term effects. Results of restoration research by CREEL along the trans-Alaska pipeline are discussed. CR 81-13

VHF ELECTRICAL PROPERTIES OF FROZEN GROUND NEAR POINT BARROW, ALASKA. Arcone, S.A., et al, June 1981, 18p., ADA-103 735, 32

refs. Delaney, A.J.

TENT, ORGANIC SOILS.

Electrical properties of frozen ground were measured using radio frequency interferometry (RFI) in the very high frequency (VHF) radiowave band.

Ice-rich organic silts and sands and gravels of variable ice content were investigated during early April of both 1979 and 1980.

Prequencies between 10 and 150 MHz were used with best results obtained between 40 and 100 MHz. Surface impedance and magnetic induction techniques were also used to obtain a separate control on vertical inhomogeneity.

Soil samples were tested for organic and water content.

The dielectric constants and water content.

The dielectric constants are the ice-rich oreanic silts ranged from 4.0 control on vertical inhomogeneity. Soil samples were tested for organic and water content. The dielectric constants determined for the ice-rich organic silts ranged from 4.0 to 5.5 while those for the sands and gravels were about 5.1. Dielectric loss was due to d.c. conduction and was very low for the silts but significant for the sands and gravels were most likely due to the higher concentrations of salt that are reported to exist in the old beach ridges in this region. All the RFI measurements are believed to be indicative of only the first few meters of the ground although the radiowaves could penetrate to tens of meters. CR 81-14

WASTEWATER TREATMENT BY A PROTO-TYPE SLOW RATE LAND TREATMENT SYS-TEM.

CR 81-15 STATISTICAL EVALUATION OF SOIL AND CLIMATIC PARAMETERS AFFECTING THE CHANGE IN PAVEMENT DEFLECTION DUR-ING THAWING OF SUBGRADES.

Chamberlain, E.J., July 1981, 10p., ADA-106 976, 7

36-975 36-975
PAVEMENTS, DEFORMATION, SEASONAL
PREEZE THAW, SUBGRADE SOILS, LOADS
(FORCES), CLIMATIC FACTORS, FROST PENETRATION, STATISTICAL ANALYSIS.

This report analyzes the results of a field study previousl reported by Scrivner et al (1969) for the National Cooperativ

Highway Research Program. These authors studied the seasonal pavement deflection characteristics of 24 test sites on roads in service in regions with freezing indexes ranging from 100F-days to 2100F-days. They used the Dynasficer cyclic pavement loading device to determine the pavement system response. Of specific interest to the analysis was the increased pavement deflection after freezing and thawing and the time to recovery of normal deflection characteristics. These characteristics were related to soil and climatic factors using statistical techniques. The most significant observations of this statistical analysis are: 1) that the freezing index is not a significant parameter in deflection during thawing, and 2) that the recovery time is inversely proportional to the depth of freezing. As was expected, the most significant variable affecting the increase in pavement deflection was the frost susceptibility classification. This observation reinforces the necessity for careful selection of soil materials used in pavement systems.

CR 81-16

COLD REGIONS TESTING OF AN AIR-TRANS-PORTABLE SHELTER.

Flanders, S.N., Aug. 1981, 20p., ADA-107 131, 9 refs. 36-1309

PORTABLE SHELTERS, TRANSPORTATION, COLD WEATHER PERFORMANCE, AIR-PLANES, TESTS.

PLANES, TESTS.

An air-transportable shelter designed and built at CRREL for use in cold regions underwent testing in Hanover, New Hampshire, and Ft. Greely, Alaska. The shelter demonstrated some of its capabilities for mobility by being towed for more than 60 miles behind various vehicles and by being transported on a C-130 cargo sirplane, a CH-47 helicopter, and a trailer truck. The shelter proved to be very easy for a crew of two to four to set up in all weather conditions including -40F cold. However, the gasoline-powered generator, which was a source for space heat as well as electricity, functioned very poorly. Overall, the prototype successfully demonstrated qualities of self-reliance, ease of operation and thermal efficiency.

SUBSEA TRENCHING IN THE ARCTIC. Mellor, M., Sep. 1981, 31p., ADA-108 341, 44 refs.

40-4673
DREDGING, OCEAN BOTTOM, PIPE LAYING, ICE SCORING, ICE ACTION, EQUIPMENT, VELOCITY, ICEBERGS, PRESSURE RIDGES, PROTECTION.

PROTECTION.

Environmental conditions are described for the continental shelf of the western Arctic, and for the shelf of Labrador and Newfoundland.

Special emphasis is given to the gouging of bottom sediments by ice pressure ridges and icebergs, and an approach to systematic risk analysis is outlined. Protection of subses pipelines and cables by trenching and direct embedment is discussed, touching on burial depth, degree of protection, and environmental impact. Conventional land techniques can be adapted for trenching across the beach and through the shallows, but in deeper water special equipment is required. The devices discussed include hydraulic dredges, submarine dredges, plows, rippera, water jets, disc saws and wheel ditchers, ladder trenchers and chain saws, routers and slot millers, ladder trenchers and chain saws, routers and slot millers, ladder dredges, vibratory and percussive machines, and blasting systems. Consideration is given to the relative merits of working with seabed vehicles, or alternatively with direct surface support from vessels or from the sea ice.

CHENA RIVER LAKES PROJECT REVEGETA-TION STUDY-THREE-YEAR SUMMARY. Johnson, L.A., et al, Oct. 1981, 59p., ADA-108 909, 22 refs.

Rindge, S.D., Gaskin, D.A. 36-2222

REVEGETATION, GRASSES, GROWTH, SOIL STABILIZATION, GRAVEL, VEGETATION, UNITED STATES—ALASKA—PAIRBANKS. VEGETATION.

UNITED STATES—ALASKA—FAIRBANKS.
During the growing seasons of 1977, 1978 and 1979, revegetation techniques were studied on the Chena River Lakes Project, a flood control dam and levee near Pairbanks, Alsaka to find an optimal treatment for establishing permanent vegetation cover on the gravel structures. The treatments tested on plots at the dam and/or levee involved three main variables: 1) vegetation (grass and clover seed and/or willow cuttings), 2) mulch, mulch blanket, and/or sludge, and 3) substrate (gravel or fine-grained soil over the gravel base). The mulches were hay, wood-cellulose-fiber, peat mosa, and Conwed Hydro Mulch 2000, which is a wood-cellulosefiber mulch with a polysaccharide tackifier. A constant rate of fertilizer was applied to all plots except the control. A section of each plot was refertilized again in their third growing season to compare annual and biannual fertilization. The high fertilization rate produced above-average growth. Pescue, brome, and foxtall were the most productive species on the dam, while slaike clover was the most productive on the wetter levee site. When grass seed and willow cuttings were planted at the same time, willow survival and growth were reduced. Fertilization is required for at least two years to produce an acceptable permanent vegetation cover, althoush fine-grained and growth were reduced. cuttings were planted at the same time, willow survival and growth were reduced. Pertilization is required for at least two years to produce an acceptable permanent vegetation cover, although fine-grained soil or sludge reduces the amount of fertilizer needed in the second year. Third-year fertilization may be necessary since the benefits of the second fertilization continue for at least two years. A sludge treatment refertilized during its second growing season produces the highest blomass recorded in this study. Sludge

from the Pairbanks treatment plant poses little, if any, danger of contamination from heavy metals or pathogens. Four-year-old seedlings of willow and native woody species growing on the dam do not have deeply penetrating root systems and therefore don't appear to pose an early threat of leakage through the dam.

LAKE ICE, ICE COVER THICKNESS, RADAR ECHOES, ICEBOUND LAKES, ICE WATER INTERFACE, SIDE LOOKING RADAR, UNITED STATES—ALASKA—NORTH SLOPE.

STATES—ALASKA—NORTH SLOPE.
Field observations support the interpretation that differences in the strength of radar returns from the ice covers of lakes on the North Slope of Alaska can be used to determine where the lake is frozen comgetely to the bottom. An ice/frozen soil interface is indicated by a weak return and an ice/water interface by a strong return. The immediate value of this result is that SLAR (side-looking airborne radar) imagery can now be used to prepare maps of large areas of the North Slope showing where the lakes are shallowed are not the SLAR flights). The bethymetry of these shallow lakes is largely unknown and is not obvious from their sizes or outlines. Such information could be very useful, for example in finding suitable year-round water supplies.

NEAR-INFRARED REPLECTANCE OF SNOW-COVERED SUBSTRATES

O'Brien, H.W., et al, Nov. 1981, 17p., ADA-110 868, 16 refs.

Koh. G 36-2431

SNOW COVER EFFECT, SOLAR RADIATION, REFLECTION, SUBSTRATES, ICE CRYSTAL OP-TICS, RADIOMETRY, METEOROLOGICAL DATA.

DATA.

The reflection of solar radiation by a snow cover in situ and the apparent influence of selected substrates were examined in wavelength bands centered at 0.81, 1.04, 1.10, 1.30, 1.50 and 1.80 micrometers. Substrates included winter wheat, timothy, corn. affalfa, grass, concrete and subsurface layers of "crusty" snow and ice. Reasonable qualitative agreement between measurements and theoretical predictions was demonstrated, with indications of quantitative agreement in the definition of a "semi-infinite depth" of snow cover. It was concluded that ultimate quantitative agreement between theory and measurement will require that an "optically effective grain size" be defined in terms of physically measurable dimensions or meteorologically predictable characteristics of the ice crystals composing the snow pack.

CR 81-22

ICE DISTRIBUTION AND WINTER SURFACE CIRCULATION PATTERNS, KACHEMAK BAY, ALASKA.

Gatto, L.W., Dec. 1981, 43p., ADA-110 806, 20 refs. 36-2432

ICE CONDITIONS, SEA ICE DISTRIBUTION, OCEAN CURRENTS, SUSPENDED SEDI-MENTS, REMOTE SENSING, LANDSAT, UNIT-ED STATES—ALASKA—KACHEMAK BAY.

Development of the hydropower potential of Bradley Lake, Alaska, would nearly double winter freshwater discharge from Alaska, would nearly double winter freshwater discharge from the Bradley River into upper Kachemak Bay, and the Corps of Ragineers is concerned about possible subsequent increased ice formation and related ice-induced problems. The objectives of this investigation were to describe winter surface circulation in the bay and document ice distribution patterns for predicting where additional ice might be transported if if forms. Fifty-one Landsat MSS band 5 and 7 and RBV images with 70% cloud cover or less, taken between 1 November and 30 April each year, were analyzed for the eight winters from 1972 to 1980 with standard photointer-pretation techniques. Results of this analysis showed that glacial sediment discharged into Kachemak Bay acts as a natural tracer in the water. Inner Kachemak Bay circulation in the winter is predominantly counterclockwise, with northeasterly nearshore currents along the south shore and southwesterly nearshore currents along the north shore. Most of the ice in the inner bay forms at its northeast and and is discharged by the Fox, Sheep and Bradley Rivers. Some ice becomes shorefast on the tidal flats at the head of the bay, while some moves southwestward along the north above pushed by winds and currents.

CB \$1.23 EVALUATION OF A COMPARTMENTAL MODEL FOR PREDICTION OF NITRATE LEACHING LOSSES.

Mehran, M., et al, Dec. 1981, 24p., ADA-111 560, 41

Tanji, K.K., Iskandar, I.K.

WASTE TREATMENT, LEACHING, LAND REC-LAMATION, WATER FLOW, SOIL CHEMISTRY, MODELS.

A model is presented that consists of a water flow submodel and a nitrogen flow submodel. Irrigation, precipitation, evapotranspiration, surface return flow, and deep percolation are considered in the water flow submodel. The processes of nitrification, denitrification, mineralization, immobilization, plant uptaks, and nitrogen fination are included in the nitrogen flow submodel. The model has been applied to two sets of experimental data obtained from 1) controlled test cells at U.S. Army Cold Regions Research and Bujineering Laboratory in Hanover, New Hampshire, and 2) field plots of the University of California at Davis. Comparison between the experimental and model results indicates the potential capabilities of compartmental models in predicting nitrogen behavior in soil-water-plant systems under wastewater land treatment operations. This model is applicable to slow rate, rapid infiltration, and overland flow systems. of nitrification, denitrification, mineralization, immobilization

CR 81-24 TRANSIENT ANALYSIS OF HEAT TRANSMIS-SION SYSTEMS.

Phetteplace, G., Dec. 1981, 53p., ADA-112 365, Refs. p.46-47. 36-2753

HEAT LOSS, UNDERGROUND PIPELINES, HEATING, PUMPS, TEMPERATURE EFFECTS, ANALYSIS (MATHEMATICS, COST ANALYSIS,

SOIL TEMPERATURE, COMPUTER GRAMS.

This report develops a method of analysis for heat transmission systems operating under district heating load conditions. The use of thermal energy storage systems is outlined and advantages are given. The method accounts for the effects of heat source and load characteristics. The transmission model itself considers the following technical aspects: 1) Selectional resource loads in sidile success? model itself considers the following technical aspects: 1) frictional pressure losses in piping systems, 2) pump characteristics, 3) pump driver characteristics, and 4) heat losses from the buried piping. The capital costs considered are the piping system and necessary pumps. Operation and maintenance costs include cost of heat loss and cost of pumping energy input. Allowances are also made for system maintenance and repair over the assumed lifetime. The heat transmission problem is formulated in the forms of a two-dimensional population problem. The decision variables are pipe diameter and supply temperature. The problem dimensional process is formusated in the forms of a two-dimensional optimization problem. The decision variables are pipe diameter and supply temperature. The problem is solved by direct search techniques using a Hooke-Jeeves pattern search algorithm. Parametric results are presented along with suggestions for further work.

CR 81-25 APPLICATION OF THE HEAT BALANCE INTE-GRAL TO CONDUCTION PHASE CHANGE PROBLEMS.

Lunardini, V.J., Dec. 1981, 14p., ADA-112 813, 15 refs.

36-2669 THERMAL CONDUCTIVITY, PHASE TRANSFORMATIONS, HEAT TRANSFER, FREEZE THAW CYCLES, FROZEN GROUND PHYSICS, STEFAN PROBLEM, HEAT FLUX, ANALYSIS (MATHEMATICS), COMPUTER APPLICATIONS, CONVECTION.

TIONS, CONVECTION.

The problem of heat conduction with phase change—often called the Stefan problem—includes some of the most intractable mathematical areas of heat transfer. Exact solutions are extremely limited and approximate methods are widely used. This report discusses the collocation method for the heat belance integral approximation. The method is applied to some standard problems of phase change—Neumann's problem—and a new solution is presented for the case of surface convection for a semi-infinite body. Numerical results are given for soil systems and also for materials of interest in latent heat thermal storage.

CR 81-26 MECHANICS OF CUTTING AND BORING. PART 7: DYNAMICS AND ENERGETICS OF AXIAL ROTATION MACHINES.

Melior, M., Dec. 1981, 38p., ADA-113 931, 10 refs. 36-3110

DRILLS, PERMAPROST, ROCK DRILLING, EQUIPMENT, THERMAL EFFECTS, DRILLING FLUIDS, ANALYSIS (MATHEMATICS).

This report deals with force, torque, energy and power in machines such as drills and boring devices, where the cutting head rotates about a central axis while penetrating parallel to that axis. Starting from a consideration of the forces

developed on individual cutting tools, or segments of cutters, the thrust and torque on a complete cutting head is assessed, and simple relationships between thrust and torque are derived. Similarly, the energy and power needed to drive the cutting head are estimated and related to tool characteristics. sign characteristics of existing machines are compiled and analyzed to give indications of thrust, torque, power, effective tool forces, nominal thrust pressure, power density, and specific

CR 81-27 SEDIMENTOLOGICAL CHARACTERISTICS AND CLASSIFICATION OF DEPOSITIONAL PROCESSES AND DEPOSITS IN THE GLACIAL ENVIRONMENT.

Lawson, D.E., Dec. 1981, 16p., ADA-113 261, 33 refs

GLACIAL DEPOSITS, GLACIOLOGY, SEDI-MENTATION, GLACIER OSCILLATION, PERI-GLACIAL PROCESSES, GLACIER FLOW, ENVI-RONMENTS, CLASSIFICATIONS

Existing classifications for deposits in the glacial environment are inadequate and inconsistent. Deposits should be classiare inadequate and inconsistent. Deposits should be classified both descriptively and genetically; adequate descriptive classifications already exist. A major problem for previous genetic classifications has been that glacial deposition and the resulting deposits properties were poorly understood. On the basis of three criteria—sediment source, uniqueness to the glacial environment, and preservation of glacier-derived properties—deposits in the glacial environment result from to the glacial environment, and preservation of glacier-derived properties—deposits in the glacial environment result from either of two groups of processes: primary or secondary. Primary processes release the debris of the glacier directly and form deposits that may bear properties related to the glacier and its mechanics. Their deposits are classified genetically as till and are the only deposits indicative of glaciation. In contrast, secondary processes mobilize, rework, transport and resediment debris and deposits in the glacial environment. They develop new, nonglacial properties in their deposits, while destroying or substantially modifying glacier-derived properties. Interpretation of their properties may provide information on the depositional process and/or the local depositional environment. Secondary deposits are resedimented and therefore not till. They are classified genetically according to the depositional process just as they are in other sedimentary environments. This genetic classification differs from previous classifications in that not all diamictons deposited in the glacial environment are classified as till; it is based strictly on process-related criteria. The origin of properties of glacial deposits in relation to glacier mechanics and environment must be recognized if the mechanisms and depositional processes of former glaciers are to be precisely understood.

ALASKA GOOD FRIDAY EARTHQUAKE OF

w, G.K., Feb. 1982, 26p., ADA-113 800. 36-2838

EARTHQUAKES, FROZEN GROUND STRENGTH, DAMAGE, ICE SHEETS, ROCK MECHANICS, STRUCTURES, WATER WAVES, UNITED STATES—ALASKA—ANCHORAGE.

On 27 March 1964, a major earthquake struck Southern Alaska. The city of Anchorage, which contained a large part of Alaska's population, suffered loss of life and destruction of property. The time of the day, the season, and ground conditions were such that loss of life and property was minimized. The frozen ground and the ice on fresh water bodies responded to the earthquake shocks in a seldom-observable pattern, which was noted and recorded. Changes of sea level and slides into the sea were responsible for waterfront destruction. It is concluded that the main factor that limited structural damage was the frozen state of the ground.

CR 82-02 DEVELOPMENT OF A RATIONAL DESIGN PROCEDURE FOR OVERLAND FLOW SYS-TEMS.

Martel, C.J., et al, Feb. 1982, 29p., ADA-113 762, 22

Jenkins, T.F., Diener, C.J., Butler, P.L.

SEWAGE TREATMENT, WATER TREATMENT, WASTE TREATMENT, FLOODING, DESIGN.

WASIE IREALIMENT, FLOODING, DISIGN.
This report describes the development of a new design procedure for overland flow systems that is based on hydraulic detention time, a familiar concept in wastewater treatment process design. A two-year study was conducted at Hanover, New Hampshire, on a full-scale overland flow site to obtain performance data in relation to detention time. Kinetobtain performance data in relation to detention time. Kineticic relationships were developed for removal of biochemical oxygen demand, total suspended solids, ammonia, and total phosphorus. Also, an empirical relationship was developed to predict hydraulic detention time as a function of application rate, terrace length, and alope. These relationships were validated using published data from other systems. An advantage of the new procedure, which should significantly reduce site preparation costs, is that it allows overland flow systems to be designed for a wide range of site conditions as long as detention time requirements are met. ICE FORMATION, TIME FACTOR, ICEBOUND

RIVERS, ANALYSIS (MATHEMATICS). The conditions that lead to initial breakup of a solid ice cover on a river due to rapid water level variations are analyzed. The analysis is based on the theory of beams on an elastic foundation. First cracking is assumed to occur when the bending moment induced in the ice cover by the wave exceeds the flexural strength of the ice cover.

CR 82-04 SEA ICE DRAG LAWS AND SIMPLE BOUND-ARY LAYER CONCEPTS, INCLUDING AP-PLICATION TO RAPID MELTING. McPhee, M.G., Feb. 1982, 17p., ADA-113 542, 24

refs.

36-2839 SEA ICE, DRIFT, BOUNDARY LAYER, ICE MELTING, STRESSES, TURBULENT FLOW, VELOCITY, VISCOSITY, BUOYANCY, MATH-EMATICAL MODELS.

EMATICAL MODELS.
Several proposed methods for treating the momentum flux between drifting ses ice and the underlying ocean are interpreted in terms of simple planetary-boundary-layer (PBL) turbulence theory. The classical two-layer approach, in which the solution for a thin surface layer is matched to an Ekman solution for the outer layer, is used to derive several forms for the drag law. These forms range from linear (where stress is proportional to relative speed), through quadratic drag on geostrophic wind in the atmosphere. Only formulations which conform with Roseby-similarity scaling are consistent with free-drift data from the 1975 AIDJEX drift station experiment. We show how a two-layer model, in thickness, provides an analytic solution for the steady-state PBL equation quite similar to recent numerical solutions. The theory is extended to include drag reduction due to buoyancy from rapid melting and is shown to agree with atmospheric results for geostrophic drag under analogous conditions of radiational cooling. The theory provides a basis for estimating trajectories and melt rates of floes drifting into water warmer than the ice melting temperature.

CR 82-05 ON THE TEMPERATURE DISTRIBUTION IN AN AIR-VENTILATED SNOW LAYER. Yen, Y.-C., Mar. 1982, 10p., ADA-115 598, 9 refs.

39-1263

39-103 SNOW TEMPERATURE, HEAT TRANSFER, MASS TRANSFER, TEMPERATURE GRADI-BUTION, DIURNAL VARIATIONS, ANALYSIS (MATHEMATICS).

(MATHEMATICS).

The problem of simultaneous heat and mass transfer in a homogeneous snow layer, with one side kept at its initial temperature and the other side with a step temperature increase, was solved for the case of constant through-flow conditions. An experimentally determined effective thermal conductivity function, i.e. Ke=0.0014+0.58 G (where G is dry mass flow rate of air in g/cm2s), was employed in the solution. The computed nondimensional temperature distribution agreed quite well with experimental data taken under pseudo-steady state conditions with the exception of the temperature for the lowest flow rate used in the experiment. The pronounced nonlinearity of the temperature distribution was found to be a strong function of the flow rate. For sinusoidal variation of atmospheric pressure, the responding flow in the snow medium was also found to be sinusoidal. In conjunction with the diurnal temperature change, this variation facilitated the process of repeated sublimation and condensation in alternate directions and thereby produced a surface layer of approximately constant snow density. surface layer of approximately cons

CR 82-06 MEASUREMENT OF GROUND DIELECTRIC PROPERTIES USING WIDE-ANGLE REFLEC-TION AND REFRACTION.

GATION.

The interpretation of continuous radar profiles requires an alternative geophysical means of obtaining ground dielectric information. Ground dielectric properties were measured using wide-angle reflection and refraction (WARR) soundings with a ground-probing radar set that transmits pulses of a few nanoseconds duration. The investigations, carried out over sandy gravel in interior Alaska, provided dielectric data to about a 5-m depth. The WARR soundings were displayed as individual traces allowing interference between sperate events and dispersion to be observed, and the soundings were compared with continuous radar and resistivity profiles conducted concurrently to extract the maximum

amount of dielectric information. The dielectric constants, derived mainly from the direct ground waves propagating along the surface, ranged from 2.9 to 7.4. Dielectric values interpreted for one site predicted the possibility of a refracted event which may have occurred during one of

EVALUATION OF METHODS FOR CALCULATING SOIL THERMAL CONDUCTIVITY.

Farouki, O., Mar. 1982, 90p., 24 refs. 37-221

FROZEN GROUND PHYSICS, THERMAL CON-DUCTIVITY, PERMAFROST HEAT TRANSFER, SOIL COMPOSITION, SOIL WATER, COMPUT-ER PROGRAMS, TESTS.

ER PROGRAMS, TESTS.

A detailed analysis of methods for calculating the thermal conductivity of soils is presented, and trends in the predictions of these methods are compared. The influence of changes in the moisture content on the calculated thermal conductivity of a soil is shown, as is the sensitivity of this calculated value to changes in dry density or in the soil solids' thermal conductivity. The methods are evaluated to determine the extent of agreement of their predictions with measured values obtained on soils of known composition and properties. The deviations of the predicted values are determined for soils that are unfrozen or frozen, coarse or fine, unsaturated, saturated or dry. The applicability of each of the methods under various conditions is determined and recommendations are made as to the best method for each condition.

CR 82-09 MODEL STUDY OF PORT HURON ICE CONTROL STRUCTURE; WIND STRESS SIMULA-

Sodhi, D.S., et al, Apr. 1982, 27p., ADA-115 417, 14

Calkins, D.J., Deck, D.S.

36-3111 ICE CONTROL, LAKE ICE, WATER PRESSURE, WIND PRESSURE, WATER FLOW, SHEAR STRESS, ICE NAVIGATION, PORTS, MODELS. STRESS, ICE NAVIGATION, PORTS, MODELS. This study deals with the distribution of forces along the converging boundaries of the Port Huron, Michigan, region where unconsolidated ice in Lake Huron is held against wind and water streases. An experimental basin was built to induce uniform ahear stress on the model ice cover by flowing water beneath the ice. The boundary segments, which held the ice cover in the region, were instrumented to measure force in the normal and tangential directions. The distribution of normal forces along the boundary was compared with a distribution derived by using a theoretical model. An ice control structure (ICS) was installed in the basin and experiments were conducted to measure the forces on the ICS and the ice release through the opening in the ICS during simulated ship passages. The experimental results are presented in a nondimensional form. In addition, the force per unit length on the ICS and the area of ice released through its opening were estimated for the expected wind conditions at the Port Huron site.

LABORATORY MEASUREMENTS OF SOIL ELECTRIC PROPERTIES BETWEEN 0.1 AND 5 GHZ.

From a high-quality set of velocity, temperature, and humidity profiles collected upwind and downwind of a step change in surface roughness, temperature, and moisture, upwind and downwind values of the heat fluxes and friction velocity are calculated.

NUMERICAL SOLUTIONS FOR A RIGID-ICE MODEL OF SECONDARY FROST HEAVE O'Neill, K., et al, Apr. 1982, 11p., ADA-115 597, For another version see 36-54. 11 refs.

39-1266 39-1266
FROST HEAVE, SOIL FREEZING, ICE MODELS, REGELATION, ICE FORMATION, GROUNDED ICE, HEAT TRANSFER, MASS TRANSFER, THERMODYNAMICS, ANALYSIS (MATH-EMATICS).

In this paper, frost heave is analyzed for the common case in which some ice penetrates the soil. In this situation, heave is due to the accumulation of soil-free ice just within the frozen zone, behind a frozen fringe of finite thickness. Heat and mass transport within and across that fringe are crucial processes in the dynamics of heave. This analysis concentrates on activity within the fringe, also connecting that activity to heat and mass flows in the more frozen and unfrozen zones. Bach component in a set of governing differential equations is developed from rational physics and thermodynamics, using previous experimental work. Is assumed that the soil ice grows through, interconnected interstices; hence it constitutes and can move as a rigid body. When this assumption is translated into mathematical terms, it completes the governing equations. The model resulting from these considerations is a one-dimensional finite element computer program that solves the equations for arbitrary initial and boundary conditions. The model is used to simulate the heave history of a hypothetical soil column frozen unidirectionally and subjected to a surcharge. The results are gratifying in that they predict qualitatively the characteristics of numerous laboratory observations. Some questions about the completeness of the theory remain, and strict verification of the model awaits further experimentation and better parameter identification.

COMPARATIVE ANALYSIS OF THE USSR CONSTRUCTION CODES AND THE US ARMY TECHNICAL MANUAL FOR DESIGN OF FOUNDATIONS ON PERMAPROST. Fish, A.M., May 1982, 20p., ADA-116 234, 27 refs. 39-1267

PERMAPROST BENBATH FROZEN GROUND SETTLING, COLD WEATH-ER CONSTRUCTION, FOUNDATIONS, PILES, DESIGN CRITERIA, BUILDING CODES, FROZ-EN GROUND STRENGTH, SAFETY, USSR

A comparative study was made of design criteria and analytical methods for footings and pile foundations on permafrost

employed in U.S.S.R. Design Code SNiP 11-18-76 (1977) and U.S. Army Cold Regions Research and Engineering Laboratory Special Report 80-34 developed in the early 1970's by the U.S. Army Corps of Engineers and published in 1980. The absence of adequate constitutive equations for frozen soils and of rigorous solutions of the boundary problems has made it preseasors to incorporate (erribicity problems has made it preseasors to incorporate (erribicity). or trozen sous and or rigorous solutions of the boundary problems has made it necessary to incorporate (explicitly or implicitly) various safety factors in the foundation analyses. From the review it is concluded that the principal difference between these practices is in the assessment and application of appropriate values of safety factors, which leads to a substantial discrepancy in the dimensions and cost of footings and pile foundations in permafrost.

RELATIONSHIP BETWEEN THE ICE AND UN-FROZEN WATER PHASES IN FROZEN SOIL AS DETERMINED BY PULSED NUCLEAR MAGNETIC RESONANCE AND PHYSICAL DE-SORPTION DATA.

Tice, A.R., et al, June 1982, 8p., ADA-118 486, 14

GROUND, NUCLEAR MAGNETIC RESONANCE, UNFROZEN WATER CONTENT, SOIL TEMPERATURE.

TEMPERATURE.

An experiment is described that demonstrates the balance between the ice and the unfrozen water in a frozen soil as water is removed.

Nuclear magnetic resonance (NMR) is used to monitor the unfrozen water content as the soil is dehydrated by a molecular siver material.

Our results show that the unfrozen water content of a Morin clay soil remains constant until the total water content has been reduced to the point where no ice remains in the system. Once the ice is depleted, the unfrozen water content determined by NMR corresponds to the toal water content of the soil determined by the weight of water removed by the molecular sieve material.

Thus the validity of utilizing NMR in determining unfrozen water contents we temperature NMR in determining unfrozen water contents vs temp

APPLICATION OF A NUMERICAL SEA ICE MODEL TO THE EAST GREENLAND AREA. Tucker, W.B., Aug. 1982, 40p., ADA-120 659, For another version see 36-3254. 37 refs.

CURRENTS, WIND FACTORS, GREENLAND.

CURRENTS, WIND FACTORS, GREENLAND.

A dynamic-thermodynamic sea ice model which employs a viscous-plastic constitutive law has been applied to the Bast Greenland area. The model is run on a 40-km spatial scale at 1/4-day time steeps for a 60-day period with forcing data beginning on 1 October 1979. Results tend to verify that the model predicts reasonable thicknesses and velocities within the ice margin. Thermodynamic ice growth produces excessive ice extent, however, probably due to inadequate parameterization of oceanic heat flux. Ice velocities extent the first order are also not well simulated. produces excessive ice extent, however, probably due to inadequate parameterization of oceanic heat flux. Ice velocities near the free ice edge are also not well simulated, and preliminary investigations attribute this to an improper wind field in this area. A simulation which neglects ice strength, effectively damping ice interaction with itself and allowing no resistance to deformation, produces excessive defit toward the coast and results in unrealistic nearshore thicknesses. A dynamics-only simulation produced reasonable results, including a more realistic ice extent, but the need for proper thermodynamics is also apparent. Other simulations verify that ice import from the Arctic Basin, and ice transport due to winds and currents, were also important components in the model studies.

SEISMIC SITE CHARACTERIZATION TECH-NIQUES APPLIED TO THE NATO RSG-11 TEST SITE IN MUNSTER NORD, FEDERAL REPUB-LIC OF GERMANY.

Albert, D.G., July 1982, 33p., ADA-119 390, 15 refs. 39-1269 SBISMIC REFRACTION, GEOLOGIC STRUCTURES, WAVE PROPAGATION, SEISMOLOGY,

VELOCITY.

VELOCITY.
Seismic P and SH wave refraction experiments at the NATO RSG-11 test site in Minnser Nord, Federal Republic of Germany, reveal the presence of a nearly horizontal, three-layer velocity structure. The upper layer, composed of unconsolidated glacial till, is 1 m thick and has P (compressional) and SH (shear-horizontal) wave velocities of 240 and 165 m/s. The second layer, made up of similar, more compacted material, is 9.5 m thick, with a P wave velocity of 470 m/s and an SH wave velocity of 159 m/s. The third layer, interpreted as the groundwater table, is located at a depth of 10.5 m and has a P wave velocity of 1590 m/s. The SH wave velocity of this layer is controlled by the matrix material and is the same as that of the second layer. A single, unreversed observation indicated fourth layer at a depth of about 20 m, but the existence of this layer remains unconfirmed. The observed fundamental mode Love wave dispersion is in agreement with the theoretical dispersion predicted by the refraction velocities. Computed partial derivatives of phase velocity with respect to shear wave

velocity show, for the frequencies observed, that the dispersion confirms the thicknesses and velocities of the two upper layers and is not affected by the deeper structure.

OPTIMIZING DEICING CHEMICAL APPLICA-TION RATES.

dinsk, L.D., Aug. 1982, 55p., ADA-119 681, 8 refs. 39-1270

CHEMICAL ICE PREVENTION, ICE CONTROL, SALTING, ROAD ICING, SNOW REMOVAL, ICE REMOVAL, SAFETY, FRICTION, TRAFFICA-

BILITY.

Snow and ice control on highways has come to rely heavily on the sodium chloride to maintain a trafficable surface for unimpeded movement. Empirical approaches have led to a wide range of application rates, some clearly excessive, but justified on the ground of safety and expediency. The combination of environmental degradation from the huge quantities of salt entering the environment, along with the increased cost of salt itself and the cost of its application have spurred the search for more precise knowledge of the proper amount of salt to apply to a pavement, considering a range of environmental, traffic and chemical parameters Since controlled tests in the field are extremely difficult to make, a circular test track of three test pavements, dense-graded saphaltic concrete (OGA) and portland cement concrete (PCC), was concrete (OGA) and portland cement concrete (PCC), was constructed in a coldroom. Natural snow and ice were applied to the pavements and an instrumented alipping wheel was crete (OGA) and portland cement concrete (PCC), was constructed in a coldroom. Natural snow and ice were applied to the pavements and an instrumented slipping wheel was driven over the surfaces to generate frictional forces. These forces were measured and then used to evaluate the response to salt application with time for three test temperatures. OGA had the lowest friction values at a temperature near the freezing point, but higher initial values or more rapidly increasing values than DGA and PCC following salt application rate of salt on PCC and DGA lies between 100 and 300 lb/lane mile (I.M.) and a bisher rate resulted in slight or no improvemile (LM), and a higher rate resulted in slight or no improve-ment in friction. DGA showed anomalous results: lower friction for 300 lb/LM and higher friction for both 100 and 500 lb/LM.

CR 82-19 WASTEWATER APPLICATIONS IN FOREST ECOSYSTEMS.

McKim, H.L., et al, Aug. 1982, 22p., ADA-119 994, 38 refs.

WASTE DISPOSAL, WASTE TREATMENT, WATER TREATMENT, FOREST ECOSYSTEMS, TREES (PLANTS), GROWTH, LAND RECLAMA TION, REVEGETATION, WATER POLLUTION.

Under proper design and management, a forest ecosystem in the central United States should renovate municipal was-towater as long or longer than conventional agricultural systems, especially when design limitations are hydraulic loading rate, heavy metals, P and N. Forest systems require smaller buffer zones than agricultural systems and lower sprinkler pressures. Immature forests are better wastewater renovators than mature forests.

CR 82-20 DECELERATION OF PROJECTILES IN SNOW. Albert, D.G., et al, Aug. 1982, 29p., ADA-119 676, 11 refa.

Richmond, P.W. 39-1271

SNOW DENSITY, PENETRATION TESTS, PRO-JECTILE PENETRATION, MILITARY SEARCH, VELOCITY, IMPACT STRENGTH.

SEARCH, VELOCITY, IMPACT STRENGTH. Instrumented M374 projectiles were launched into snow, nylon, and Styrofoam targets using a 10.7-m radius centrifuge. For snow of 410-kg/cu m density, the 3.1-kg test projectile experienced decelerations of approximately 220, 400, and 550 m/sq s (at a depth of 0.1 m) for initial impact velocities of 15, 30 and 46 m/s respectively. These values disagree with values predicted from a simple hydrodynamic drag force approximation. The decelerations measured for snow targets were always greater, than those measured for nolon ets were always greater than those measured for nylon ving targets (of density 120 kg/cu m) indicating that material is not a good analog for snow of the density

CR 82-21 ACOUSTIC EMISSIONS FROM POLYCRYS-TALLINE ICE.

St. Lawrence, W.F., et al, Aug. 1982, 15p., ADA-119 632, 18 refs.

Cole, D.M. 37-734

ICE CRYSTAL STRUCTURE, ICE ACOUSTICS, COMPRESSIVE PROPERTIES, STATIC LOADS, FRACTURING, STRESSES, STRAINS, TEMPERATURE EFFECTS, TIME FACTOR, TESTS.

The acoustic emission response from fine-grained polycrystal-line ice subjected to constant compressive loads was examined. A number of tests were conducted with the nominal stress ranging from 0.8 to 3.67 MPs at a temperature of -5 C. The acoustic emission response was recorded and the data are presented with respect to time and strain. The source of acoustic emissions in ice is considered in terms of the formation of both microfractures and visible fractures that develop without catastrophic failure of the ice. A model to describe the acoustic emission response is developed.

PHASE TRANSFORMATIONS, UNDERGROUND PIPELINES, THERMAL INSULATION, ANALYSIS (MATHEMATICS).

TION, ANALYSIS (MATHEMATICS).

The problem of thawing beneath heated structures on permafrost (or cooled structures in non-permafrost zones) musbe addressed if safe engineering designs are to be conceived.
In general there are no exact solutions to the problem of
conduction heat transfer with phase change for practical
geometries. The quasi-steady approximation is used here
to solve the conductive heat transfer problem with phase
change for insulated geometries including infinite strips, rectangular buildings, circular storage tanks, and buried pipes.

Analytical solutions are presented and graphed for a range
of parameters of practical importance.

DIRECT FILTRATION OF STREAMBORNE GLACIAL SILT.

SURVETS, EQUIPMENT.

A direct filtration, water treatment pilot plant was operated on the Kenai River at Soldotna, Alaska, during the summer of 1980. The purpose of the pilot plant operations was to determine the feasibility of the direct filtration process for removal of glacial silt. The major criterion used to determine feasibility was production of water containing less than 1.0 NTU of turbidity. For the range of raw water turbidities encountered (22-34 NTU), the pilot plant testing indicated that direct filtration was feasible and could be considered as an alternative to conventional water treatment plants containing sedimentation tanks.

SUBSEA PERMAFROST IN HARRISON BAY, ALASKA: AN INTERPRETATION FROM SEIS-MIC DATA.

Neave, K.G., et al, Aug. 1982, 62p., ADA-121 020, 16

Selimann, P.V.

Velocity data derived from petroleum industry seismic records from Harrison Bay show that high-velocity material (>2km/s) interpreted to be ice-bonded permafror is common. In the eastern part of the bay, the depth to high velocity material increases and velocity decreases in an orderly manner with increasing distance from shore until the layer is no longer apparent. The western part of the bay is less orderly, possibly reflecting a different geological and thermal history. This western part may be an inundated section of the low coastal plain characterized by the region north of Teshekpuk Lake, and could have contained deep thaw lakes, creating low velocity zones. Along some seismic lines, the high-velocity material extends approximately 25 km offshore. Velocity data derived from petroleum industry sei km offshore

COUNTERMEASURES, SURFACE TEMPERA-STATISTICAL ANALYSIS, EXPERIMEN-TATIÓN

TATION.

The thermal protection system tiles on the space shuttle Orbiter are extremely sensitive to impact damage. Such impacts could be caused by ice particles dislodged from the outer surface of the external tank (BT) during the launch. The BT, which contains the cryogenic propellant tanks, is covered with a spray-on foam insulation (SOPT) to minimize for formation. The objective of this investigation we to experimentally explore a range of environmental condition for which significant icing potential exists for the ET. A significant finding, which became evident early in the experimental program, was that computer models based upon the average SOFT thickness predicted panel surface temperatures that were considerably higher than those observed. For an assessment of icing, the important values to characterize

the SOFI are the minimum thickness and range of thickness. Dense ice formation occurred most readily when a small portion of the total surface area had a temperature below freezing.

ALASKA—CARIBOU CREEK.

The Caribou-Poker Creeks Research Watershed is a small drainage basin located 48 km northwest of Pairbanks, Alaska. Elevations within the watershed range from 210 to 326 m, and approximately 28% of its area is underlain by permafrost. Climatic differences between the watershed and Fairbanks Climatic differences between the watershed and Fairbanks are primarily due to the higher elevation of watershed. Generally the watershed climatic sities are warmer in winter and cooler in summer than Fairbanks. An analysis of annual streamflow data showed an inconsistency of baseflow recessions from year to year. The runoff-rainfall ratio for individual summer storms averaged 0.35 for Carlbou Creek. Comparisons of apot discharge measurements of predominantly permafrost and non-permafrost subwatersheds showed that permafrost-dominated watersheds have a much "flashier" response to precipitation than non-permafrost watersheds. A com_arison of the annual flow distribution of sheds. A comparison of the annual flow distribution of the watershed indicated that Caribou Creek has lower summer and higher winter discharges per unit area than the Chena or Salcha Rivers. The temporal variability of the flow of Caribou Creek is low compared with small- and moderate-sized streams in New England.

CR 82-27 LEAST LIFE-CYCLE COSTS FOR INSULATION IN ALASKA.

Flanders, S.N., et al, Oct. 1982, 47p., ADA-122 806, 6 refs.

Coutts, H.J. 37-1482

THERMAL INSULATION, BUILDINGS, COST ANALYSIS, ECONOMIC ANALYSIS, CLIMATIC FACTORS, FUELS, MILITARY FACILITIES.

PACIORS, FUBLS, MILITARY FACILITIES.

Recommendations for economical thicknesses for building insulation result from a study of fuel and construction costs of 12 military installations in Alaska. A comparison between the insulation thickness that a building owner might choose today and what he might choose in 20 years indicates a trend for much thicker insulation in the future. An analysis of how much more expensive a building built today with the thickness that would te appropriate 20 years hence indicates only a small penalty in life-cycle costs for the additional insulation. Therefore, a minimum of R-32 walls and R-62 attics is recommended for most of Alaska.

CR 82-28 EVALUATION OF VAISALA'S MICROCORA AUTOMATIC SOUNDING SYSTEM

MARINE METEOROLOGY, METEOROLOGI-CAL INSTRUMENTS, METEOROLOGICAL

MARINE METEOROLOGY, METEOROLOGICAL INSTRUMENTS, METEOROLOGICAL
DATA, WIND (METEOROLOGY).

During the Weddell Polynya Expedition in the southern
ocean, over 60 upper-air soundings were made with a Vaisala
MicroCORA Automatic Sounding System installed on the
Soviet icebreaker Mikhail Somov. The MicroCORA system
measures the wind vector by using the Omega navaid signals
to track the balloon-borne radiosonde. This windfinding
is thus unaffected by any motions of the ground station,
the system is easy to use, and the data seem accurate.
Comparison launches, during which the Vaisala radiosonde
and the sonde of another manufacturer were carried on
the same balloon, indicate that the MicroCORA pressure
and temperature data are also of high quality. There
were problems with the MicroCORA measurement of humdity, however, because of an inordinate number of failures
of the humidity sensor, the Humicap, which is prone to
drift. After a unit-by-unit hardware evaluation of the
components of the MicroCORA a, stem, its expected reliability
for use at sea is judged only fair; several units were poorty
packaged, and servicing and repair require a high degree
of technical expertise. (Auth.)

SNOW CRYSTAL GROWTH, RECRYSTALLIZA-TION, SNOW CRUST, DEPTH HOAR, HEAT PLUX, VAPOR TRANSFER, GRAIN SIZE, THER-MODYNAMICS, SNOW DENSITY, TEMPERA-TURE EFFECTS, TEMPERATURE GRADIENTS, SNOW COVER.

loe grains in a snow cover with a low temperature gradient sesume a well-rounded equilibrium form. However, at temperature gradients of 0.1 to 0.2C/cm (depending somewhat on temperature and snow density), the rounded grains recrystalize into a faceted kinetic growth form. The large temperature gradient must play a decisive role in moving the vapor fast enough to sustain the rapid growth rate associated with the kinetic growth form. Once the large temperature gradient is removed, the grains recrystallize back to the equilibrium form. The recrystallization occurs in either direction without a change in bulk density. The growth of faceted crystals begins at the warmer base of the snow cover where the excess vapor pressure is largest. A transition between the overlying rounded grains moves upward in time. Faceted crystals also grow just below crusts of reduced permeability, where the increased vapor accumulation can sustain the excess vapor pressure needed for kinetic growth. The heat and vapor flows are described using a model based on thermodynamic equilibrium. The temperature distribution is shown to be quasi-linear at steady state in homogeneous snow. The recrystallization of the snow is modeled using the rounded grains as sources and the faceted grains as sinks. In the future this model should be extended to account for different temperatures among the sources and sinks.

EQUATIONS FOR DETERMINING THE GAS AND BRINE VOLUMES IN SEA ICE SAMPLES. Cox, G.F.N., et al, Oct. 1982, 11p., ADA-122 779, 13 refa

Information on sea ice conditions in the Bering Strait and the iceftort formation around Fairway Rock, located in the strait, is presented. Cross-sectional profiles of Fairway Rock and the relief of the iceftot are given along with theoretical analyses of the possible forces active during iceftot formation. It is shown that the ice cover most likely fails in flexure as opposed to cruahing or buckling, as the former requires less force. Field observations reveal that the Fairway Rock iceftot is massive, with ridges up to 15 m high, a seaward face only 20 deg from vertical, and interior ridge slopes averaging 33 deg. The iceftot is believed to be grounded and its width ranges from less than 10 to over 100 m. on ses ice conditions in the Bering Strait and

CR 82-32 FLUID DYNAMIC ANALYSIS OF VOLCANIC TREMOR

Ferrick, M.G., et al, Oct. 1982, 12p., ADA-122 778, 28 refs.

Qamar, A., St. Lawrence, W.F.

37-1400 FLUID DYNAMICS.

SEISMOLOGY. ANOES, EARTHQUAKES, ICEQUAKES, GEO-MAGNETISM

MAGNETISM.

Low-frequency (< 10 Hz) volcanic earthquakes originate at a wide range of depths and occur before, during, and after magmatic eruptions. The characteristics of these earthquakes suggest that they are not typical tectonic events. Physically analogous processes occur in hydraulic fracturing of rock formations, low-frequency lecquakes in temperate glaciers, and autoresonance in hydroelectric power stations. We propose that unsteady fluid flow in volcanic conduits is the common source mechanism of low-frequency volcanic earthquakes (tremor). The fluid dynamic source mechanism explains low-frequency earthquakes of arbitrary duration, magnitude, and depth of origin, as unsteady flow is independent of physical properties of the fluid and conduit. Fluid transients occur in both low-viscosity gases and high-viscosity liquids. A fluid transients can be formulated as generally as is warranted by knowledge of the composition and physical properties of the fluid, material properties, geometry and roughness of the conduit, and boundary conditions.

CR 82-33 ON THE DIFFERENCES IN ABLATION SEA-SONS OF ARCTIC AND ANTARCTIC SEA ICE. Andreaa, E.L., et al, Oct. 1982, 9p., ADA-122 454, 41 refs. For another source see 36-2836 (MP 1517). Ackley, S.F. 39-1728

SEA ICE, ICE MELTING, ABLATION, METEOROLOGICAL FACTORS, ICE CONDI-

TIONS.

Arctic sea ice is freekled with melt ponds during the ablation season; Antarctic sea ice has few, if any. On the basis of a simple surface heat budget, we investigate the metocrological conditions necessary for the onset of surface melting in an attempt to explain these observations. The low relative humidity associated with the relatively dry winds off the continent and an effective radiation parameter smaller than that characteristic of the Arctic are primarily responsible for the absence of melt features in the Antarctic. Together these require a surface-layer air temperature above 0 C before Antarctic sea ice can melt. A ratio of the bulk transfer coefficients C(B)/C(B) less than I also contributes to the dissimilarity in Arctic and Antarctic ablation seasons. The effects of wind speed and of the sea-ice roughness on the absolute values of C(H) and C(B) seem to moderate regional differences, but final assessment of this hypothesis awaits better data, especially from the Antarctic.

HYDRAULIC MODEL STUDY OF PORT HURON ICE CONTROL STRUCTURE. Calkins, D.J., et al, Nov. 1982, 59p., ADA-123 715, 8

FLOES, DOPED ICE, PORTS, MODELS.

The ice discharge through an opening in an ice control structure was documented to be a function of the floe size, ice type, ice floe conditions and vessel direction. The model data for the average ice discharge per vessel transit scaled to prototype values compared favorably with data taken at the St. Marys River ice control structure (ICS). The model results of the force measurements were also consistent with data taken at the St. Marys ICS. The dynamic loading conditions were independent of vessel direction. The dynamic loading to the structure using 3 types of ice (plastic, natural and urea-doped) showed a considerable tion. The dynamic loading to the structure using 3 types of ice (plastic, natural and uret-doped) showed a considerable difference in their means and standard deviations. The urea-doped ice was evaluated for dynamic loading conditions, and reasonable peak values of 3 to 5 times the mean load at each measuring position were recorded, independent of vessel direction. It appears that synthetic random ice floes may be used in model studies where ice discharge through an opening in a structure needs to be documented. This study shows the synthetic random ice floe discharge to fall reasonably within the values obtained for natural ice discharge for both rafted and non-rafted ice fields above the ICS. However, the question of whether synthetic ice can be used for analyzing force distribution and dynamic force loading criteria cannot be fully answered at this time because the load distributions of the synthetic and natural floes appear to differ.

CR 82-35 CLIMATE OF REMOTE AREAS IN NORTH-CENTRAL ALASKA: 1975-1979 SUMMARY. Haugen, R.K., Nov. 1982, 110p., ADA-123 719, 31

GLIMATE, SNOW ACCUMULATION, PRECIPITATION (METEOROLOGY), AIR TEMPERATURE, TEMPERATURE, TEMPERATURE, TEMPERATURE VARIATIONS, UNITED STATES—ALASKA.

ALASKA.

Air temperature, precipitation, and some ground surface temperatures predominantly from remote areas of central and northern Alaska are statistically and graphically summarized on a monthly basis for a five-year period (1975-79). The remote site data were obtained during the course of several remote site data were obtained during the course of several CRRBL investigations. To provide a more comprehensive coverage, these data are presented together with data obtained at National Weather Service stations in the area. The analysis is based on four climatic regions within the study area: the Continental Interior, the Brooks Range, the Arctic Foothills, and the Arctic Cosstal Plain. A detailed analysis of coastal-inland summer air temperature gradients on the Arctic Cosstal Plain is given. Station histories for the 1975-79 period and tabulated air and ground temperature statistics are included as appendices. statistics are included as appendices

CR 82-36 LONG-TERM MODIFICATIONS OF PERENNI-ALLY PROZEN SEDIMENT AND TERRAIN AT EAST OUMALIK, NORTHERN ALASKA. Lawson, D.E., Nov. 1982, 33p., ADA-123 731, Refs.

p.30-33.

PERMAPROST THERMAL PROPERTIES, DEG-RADATION, SOIL EROSION, SEDIMENTS, TUNDRA, ENVIRONMENTAL IMPACT, THER-MOKARST, ACTIVE LAYER, HUMAN FACTOR ENGINEERING, UNITED STATES—ALASKA—

OUMALIK.

Camp construction and drilling activities in 1950 at the East Oumalik drill site in northern Alaska caused extensive degradation of ice-rich, perennially frozen silt and irreversible modification of the upland terrain. In a study of the long-term degradational effects at this site, the near-surface geology was defined by drilling and coring 76 holes (maximum depth of 34 m) in disturbed areas and by laboratory analyses of these cores.

Terrain disturbances, including bulldozed seology was defined by drilling and coring 76 holes (maximum depth of 34 m) in disturbed areas and by laboratory analyses of these cores. Terrain disturbances, including bulldozed roads and excavations, camp structures and off-road vehicle trails, were found to have severely distrupted the site's thermal regime. This led to a thickening of the active layer, melting of the ground ice, thas unbisdence and thaw consolidation of the sediments. Slumps, sediment gravity flows and collapse of materials on alopes bounding thaw depressions expanded the degradation laterally, with thermal and hydraulic evosion removing material as the depressions widened and deepened with time. Degradational processes became less active after thawed sediments thickened sufficiently to slow the increase in the depth of thaw and permit alope stabilization. The site's terrain is now irregular and hummocky with numerous depressions. Seasonal thaw depths are deeper in disturbed areas than in undisturbed areas and reflect the new moisture conditions and morphology. The severity of disturbance is much greater at East Oumalik than at another old drill site, Fish Creek. The difference results primarily from differences in the physical properties of the sediments, including the quantity and distribution of ground ice. In areas similar to East Oumalik, the removal or severe conscious of the vegetative mat would cause similar adverse physical changes to take place over two to three decades and should therefore be avoided.

TUNDRA, MAPPING, REMOTE SENSING, GEOBOTANICAL INTERPRETATION, ENVIRONMENTS, SOILS, PATTERNED GROUND, VEGETATION, CLASSIFICATIONS, LANDSAT, UNITED STATES—ALASKA—ARCTIC NA-TIONAL WILDLIFE REFUGE.

TIONAL WILDLIFE REFUGE.

This report presents a Landsat-derived land cover map of the northwest portion of the Arctic National Wildlife Refuge, Alaska. The report is divided into we parts. The first is devoted to the land cover map we stalled descriptions of the mapping methods and legend. The second part is a description of the study area. The classification system used for the maps is an improvement over existing methods of describing tundra vegetation. It is a comprehensive method of nomenclature that consistently applies the same criteria for all vegetation units. It is applicable for large-and small-scale mapping and is suitable for describing vegetation complexes, which are common in the patterned-ground terrain of the Alaskan Arctic. The system is applicable to Landsat-derived land cover classifications. The describing of the study area focuses on five primary terrain types: flat thaw-lake plains, hilly cosstal plains, foothills, mountainous soils and vegetation are described for each terrain types flat thaw-lake plains, and river flood plains. Topography, landforms, soils and vegetation are described for each terrain types the train types and for the 89 townships within the study areas. Two land cover maps at 1:250,000 are included.

CR 82-38 WINDOW PERFORMANCE IN EXTREME COLD.

ICING, WINDOWS, WEATHERPROOFING,
MILITARY FACILITIES, THERMAL INSULA-TION, COLD WEATHER CONSTRUCTION, HEAT LOSS, AIR LEAKAGE, HUMIDITY, CON-DENSATION, COUNTERMEASURES, COST ANALYSIS.

Extreme cold causes heavy buildup of frost, ice and condensa-tion on many windows. It also increases the incentive for improving the airtightness of windows against heat loss. Our study shows that tightening specifications for Alaskan windows to permit only 30% of the air leakage allowed by current American airtightness standards is economically

attractive. We also recommend triple glazing in much of Alsaka to avoid window icing in homes and barracka. We base our conclusions on a two-year field study of Alsaka military bases that included recording humidity and temperature data, observing moisture accumulation on windows and measuring sirtightness with a fan pressurization device. ICE SHELVES, BRINES, ICE SALINITY, ANTARCTICA—MCMURDO ICE SHELF.

A 4.4-m-high brine step in McMurdo Ice Shelf has migrated about 1.2 km in 4 years. This migration is proof of the dynamic nature of the step, which is the leading edge of a brine wave that originated at the shelf edge after a major break-out of the McMurdo Ice Shelf. The inland boundary of brine penetration is characterized by a series of descending steps that are believed to represent terminal positions of separate intrusions of brine of similar origin. The inland boundary of brine percolation is probably controlled largely by the depth at which brine encounters the firn/ice transition (43m). However, this boundary is not fixed by permeability considerations alone, since measurable movement of brine is still occurring at the inland boundary. Freeze-fractionation of the seawater as it migrates through the ice shelf preferentially precipitates virtually all sodium sulfate, and concomitant removal of water by freezing in all pore spaces of the infiltrated firn produces residual brines approximately six times more concentrated than the original seawater. YSIS (MATHEAMTICS), DESIGN.

The use of explosives to break floating ice sheets is described, and test data are used to develop curves that predict explosives effects as ice thickness, charge size, and charge depth vary. Application of the curves to practical problems is illustrated by numerical examples. The general features of underwater explosions are reviewed and related to ice blasting. Quasitatic plate theory is considered, and is judged to be inapplicable to explosive cratering of ice plates. The specific energy for optimized ice blasting is found to compare quite favorably with the specific energy of icebreaking ships. All available field data for ice blasting are tabulated in appendices, together with details of the regression analyses from which the design curves are generated. curves are general

CR 82-41 EVALUATION OF PROCEDURES FOR DETER-MINING SELECTED AQUIFER PARAMETERS. Daly, CJ., Dec. 1982, 104p., ADA-125 437, Refs. p.93-104. 37-3496

GROUND WATER, WATER FLOW, HYDROLO-GY, PERMEABILITY, WATER POLLUTION, POROSITY, TESTS.

Many of the important factors influencing the choice appropriate aquifer test procedures are presented. The concepts of bias, accuracy and spatial variability are explained. The definitions of a number of aquifer parameters are developed from basic principles demonstrating the underlying assumptions and limitations. The parameters considered are: piezometric head, hydraulic conductivity/intrinsic permeability, flow directions and the description of the descript head, hydraulic conductivity intrinsic permeability, flow direction, specific discharge magnitude, transmissivity, volumetric flow rate, total porosity, effective porosity, average linear velocity, storage coefficient, specific yield, dispersion coefficient-aquifer dispersivity. For each parameter several techniques are described, evaluated and ranked in terms of perceived potential accuracy, simplicity and value to contaminant transport studies. It must be stressed, however, that the evaluations are based principally upon theoretical grounds, and not upon actual conduct of the desribed procedures.

CR 82-42 EFFECTS OF CONDUCTIVITY OF HIGH-RESO-LUTION IMPULSE RADAR SOUNDING, ROSS ICE SHELF, ANTARCTICA.

ANTARCTICA—ROSS ICE SHELF.
The system was evaluated to detect sea ice on the bottom of the Ross Ice Shelf, detect the preferred horizontal casis azimuthal direction of the sea ice crystals and determine the direction of the currents under an Antarctic ice shelf. Surface radar survey on the Ross Ice Shelf at Site J-9 and surface and airforme radar profiling on the McMurdo Ice Shelf were made. The CRREL impulse radar system was unable to detect the shelf bottom at Site J-9, which drilling revealed to be 416 m below the snow surface. The radar system was used to profile the McMurdo Ice Shelf

both from the snow surface and from the air; a shelf thickness of about 275 m was easily detected. The bulk conductivity of the ice shelf at Site J-9 was higher than originally anticipated, and this limited the radar sounding depth to about 405 m when operating at a frequency of 20 MHz. TION, DESIGN, STATISTICAL ANALYSIS.

Roof snow load case studies gathered throughout the United States over a three-year period are analyzed. The objective of the analysis is to determine a relationship between the snow load on the ground and the corresponding uniform snow load on flat and sloped roofs. The main parameters considered are the thermal characterities of the roof, the roof slope and the exposure of the structure. Exposure has the strongest effect on the ratio of ground to roof snow loads. Comparisons are made with existing and proposed building codes and standards.

WASTE TREATMENT, WATER TREATMENT, LAND RECLAMATION, TEMPERATURE EF-FECTS, SLOPES, WATER POLLUTION, AB-SORPTION, WATER FLOW.

SORPTION, WATER FLOW.

The removal efficiency for 13 trace organics in wastewater was studied on an outdoor, prototype overland flow land treatment system. The removal for each of these substances was greater that 94% at an application rate of 0.4 cm/hr. The percent removals declined as application rates were increased. The rate of removal from solution was described by the sum of two mass-transport-limited, first-order rate coefficients representing volatilization and sorption. A model based on the two-film theory was developed; the observed removal rate coefficients were regressed against three properties of each substance: the Henry's constant, the octanol-water partition coefficient and the molecular weight. The dependence of the removal process on temperature was studied and is included along with average water

depth in the model. The decrease in removal rate as temperature declined is supported by the known dependence of Henry's constant and diffusivity on temperature. The model was validated on a second overland flow system. The surface soil concentrations of the trace organics determined Ine surface soil concentrations of the trace organics determined at the end of the experiment suggest that a secondary mechanism renews the surface activity rapidly enough so that contaminants do not build up on the surface, with the possible exception of PCB. Biodegradation is suggested as the predominant secondary mechanism rather than volatilization because substances less volatile than PCB were not found at the end of the experiment.

ICE GROWTH ON POST POND, 1973-1982. Gow, A.J., et al, Feb. 1983, 25p., ADA-126 334, 15

ICE GROWTH, ICE DETERIORATION, PONDS, SNOW ICE, ICE COVER THICKNESS, METEOROLOGICAL FACTORS, SEASONAL VARIATIONS, ICE MODELS, DEGREE DAYS, STEFAN PROBLEM, UNITED STATES—NEW HAMPSHIRE—POST POND.

STEFAN PROBLEM, UNITED STATES—NEW HAMPSHIRE—POST POND.

Measurements and analysis of seasonal ice growth and decay on Post Pond, New Hamsphire, for the period 1973-1982 are presented. Observations included ice thickness measurements, examination of the various ice types contributing to the ice cover, and measurements of meteorological parameters for correlation with and modeling of the ice growth process. The overall nature of ice growth and decay (ice loss) on Post Pond has been ascertained, the seasonal variability in the timing of freeze-up and ice-out and the duration of the ice cover have been determined, and the relationship of ice growth to freezing-degree-day records evaluated on the basis of a Stefan conduction equation modified to deal with ice sheets covered with or free of snow. Ice growth occurs predominantly by the direct freezing of lake water, but snow ice may compose as much as 50% of the ice cover in winters with higher than average snowfall. Freeze-up leading to the establishment of a stable ice cover occurs during the 4-week period from the end of November to the end of December. Maximum seasonal ice thicknesses were from 45 to 67 cm and are generally attained during the first two weeks of March; ice-out, marking the final disappearance of ice from Post Pond, usually occurs by the third week of April. The overall rate of ice loss is three to four times that of ice growth, and is dominated initially by melting from the top. As much as 50% of the ice may be lost in this way before the onset of any bottom melting. Final dissipation of the ice cover is usually expedited by canding resulting from preferential melting and disintegration of the ice at crystal boundaries.

ICE SOLID INTERFACE, OFFSHORE STRUCTURES, PILE STRUCTURES, ICE PRESSURE, DYNAMIC LOADS, ICE LOADS, VELOCITY, TESTS.

TESTS.

This report presents the results of dynamic ice-structure interaction model tests conducted at the CRREL Ice Engineering Facility. A flexible, single-pile, bottom-founded offshore structure was simulated by a test pile with about a one-to-ten scale ratio. Ures (instead of sodium chloride) was used as dopant to scale down the ice properties, resulting in good model ice properties. Six ice fields were frozen and 18 tests carried out. In all cases distinctive dynamic ice-structure interaction vibrations appeared, from which abundant data were collected. In tests with linear ice velocitys sweep, sawtooth-shaped ice force fluctuations occurred frust. With increasing velocity the natural modes of the test pile were excited and shifts from one mode to another occurred. sweep, sawtooth-shaped ice force fluctuations occurred first. With increasing velocity the natural modes of the test pile were excited, and shifts from one mode to another occurred. The maximum ice force values appeared mostly with low loading rates, but high forces appeared randomly at high core velocities. As a general trend, ice force maximums, averages and standard deviations decreased with increasing ice velocities. The aspect ratio effect of the ice force in coninuous crushing follows the same dependence as in static loadings. The frequency of observed ice forces is strongly dominated by the natural modes of the structure. Dynamically unstable natural modes tend to make the developing ice force frequencies the same as the natural frequencies.

CR 83-06 CHEMICAL FRACTIONATION OF BRINE IN THE MCMURDO ICE SHELF, ANTARCTICA. Cragin, J.H., et al, Mar. 1983, 16p., ADA-127 821, 23 refs.

Gow. A.J., Kovacs, A.

ICE CORES, ICE SALINITY, ICE COMPOSITION, ICE SHELVES, ICE PHYSICS, ANTARCTICA— MCMURDO SOUND.

During the austral summers of 1976-77 and 1978-79, several ice cores were taken from the McMurdo lee Shelf brine zone to investigate its thermal, physical and chemical properties. Chemical analyses of brine samples from the youngest (uppermost) brine wave show that it contains sea salts in normal seawater proportions. Purther inland, deeper and

older brine layers, though slightly highly saline (3 > 200%), are severely depleted in (S04)2-/Na+ ratio being an order of magnitude less than that of normal seawater. Analyses of Na+, K+, Ca2+, Mg2+, (S04)2- and C1-, together with solubility and temperature considerations, show that of Ni+, K+, Ca2+, Mg2+, (So4)2- and Cl-, together with solubility and temperature considerations, show that the tuiflate depletion is due to selective precipitation of mirabilite, Na2S041OH2O. The location of the inland boundary of brine penetration is closely related to the depth at which the brine encounters the firn/ice transition. However, a small but measurable migration of brine is still occurring in otherwise impermeable ice; this is attributed to eutectic dissolution of the ice by concentrated brine as it moves into deeper and warmer parts of the McMurdo Ice Shelf. DAMS, WATER FLOW, WATER WAVES, HY-DROLOGY, RIVER FLOW, FLOW MEASURE-MENT, MATHEMATICAL MODELS, DIFFU-

SION.

Peak power generation with hydropower creates tailwater flow conditions characterized by high and low flows with abrupt transitions between these states. Flows occurring in tailwaters typically form sharp-fronted, large-amplitude waves of relatively short period. An understanding of the mechanics of downstream propagation of these waves is important both for direct application in studies of the tailwater and because of the similarity of these waves to those following a dam break. An analysis of the dynamic equations of open channel flow is used to quantify the relative importance of flow wave convection, diffusion and dispersion in rivers. The relative importance of each process is related to the relative magnitude of terms in the dynamic equations, providing a physical basis for model formulation. A one-dimensional diffusion wave flow routing model, modified for tailwaters, simulates the important physical processes affecting the flow and is straightforward to apply. The model is based upon a numerical solution of the kinematic wave equation.

PROPERTIES OF UREA-DOPED ICE IN THE CREEK TEST BASIN.

ELS, AIR TEMPERATURE, TESTS.

In the course of model tests with ures-doped ice in the CRREL lee Engineering Facility test basin, the growth process and the physical and mechanical properties of the model ice were investigated. The perameters which were varied were: urea concentration in the tank water, air temperature during growth, growth duration, and tempering time. Uniformity of ice thickness and ice mechanical properties over the whole tank area were found to be satisfactory. The structure of the urea-doped ice was found to be similar to that of the ice except for a relatively thick incubation layer over a dendritic bottom layer. Empirical relationships were established between: ice thickness and negative degree-hours; mechanical properties and growth temperature, urea concentration, and ice thickness; and reduction in mechanical properties and tempering time. The results of the study are presented in charts which permit reliable scheduling of model tests with required ice thickness and ice flexural strength. trength

SHORE ICE RIDE-UP AND PILE-UP FEA-TURES. PART 1: ALASKA'S BEAUFORT SEA

Kovacs, A., Mar. 1983, 51p., ADA-127 198, 24 refs.

FAST ICE, ICE PILEUP, ICE OVERRIDE, SEA ICE, SHORES, SHORELINE MODIFICATION, BEACHES, BEAUPORT SEA.

BEACHES, BEAUPORT SEA.

Recent observations of shore ice pile-up and ride-up along the coast of the Alaska Beaufort Sea are presented. Information is given to show that sea ice movement on shore has overridden steep coastal bluffs and has thrust inland over 150 m, gouging into and pushing up mounds of beach sand, gravel, boulders and peat and, inland, the tundra material. The resulting ice scar morphology was found to remain for tens of years. Onshore ice movements up to 20 m are relatively common, but those over 100 m are very infrequent. Spring is a dangerous time, when sea ice melts away from the shore, allowing ice to move freely. Under this condition, driving stresses of less than 100 kPa can push thick sea ice onto the land.

COMPUTER MODELS FOR TWO-DIMEN-SIONAL STEADY-STATE HEAT CONDUCTION. Albert, M.R., et al, Apr. 1983, 90p., ADA-128 793, 8

Phetteplace, G.E.

PERMAPROST HEAT TRANSFER, PERMAPROST PHYSICS, FROST ACTION, THERMAL CONDUCTIVITY, UNDERGROUND PIPELINES, BOUNDARY LAYER, COMPUTER PROGRAMS, MATHEMATICAL MODELS.

This report outlines the development and verification of two computer models of two-dimensional steady-state heat conduction including a variety of boundary conditions. One is a finite difference program and the other is a finite element program. The results of each program are compared to two analytic solutions, and to one another.

RADAR PROFILING OF BURIED REFLEC-TORS AND THE GROUNDWATER TABLE. Sellmann, P.V., et al, Apr. 1983, 16p., ADA-130 225, 17 refs.

REVIEW OF THE PROPAGATION OF INELAS-

TIC PRESSURE WAVES IN SNOW. Albert, D.G., Apr. 1983, 26p., ADA-128 714, 35 refs.

SNOW BLASTICITY, EXPLOSIVES, WAVE PROPAGATION, PRESSURE, ELASTIC WAVES, DETONATION WAVES, TESTS.

DETONATION WAVES, TESTS.

A review on past experimental and theoretical work indicates a need for additional experimentation to characterize the response of snow to inelastic pressure waves. Pressure data from previously conducted explosion tests are analyzed to estimate the elastic limit of snow of 400 kg/cu m density to be shout 36 kPs. This pressure corresponds to a scaled distance of 1.6 m/kg exp 1/3 for charges fired beneath the surface of the snow, and to a scaled distance of 1.2 m/kg exp 1/3 for charges fired in the air. The effects of a soon cover on the method of clearing a minefield by using an explosive charge fired in the air shove the snow surface are also discussed and recommendations are given for further work in this area. Explosive pressure data are used to estimate the maximum effective scaled radius for detonating buried mines at shallow depth to be 0.8 kg exp 1/3. Fuel-air explosive will increase this effective radius significantly because of the increase in the size of the source region. the source region.

STUDY ON THE TENSILE STRENGTH OF ICE AS A FUNCTION OF GRAIN SIZE. Curtier, J.H., et al, May 1983, 38p., ADA-134 889, 30

LAKE WATER INTAKES UNDER ICING CON-**DITIONS**

Dean, A.M., Jr., May 1983, 7p., ADA-128 757, 52 38-4418

WATER INTAKES, ICE CONDITIONS, ICE PRE-VENTION, LAKE WATER, ICE MECHANICS, DESIGN CRITERIA, ICING.

An intake may be restricted or clogged by active frazil, passive frazil, brash, or a combination of these ice forms. The exact nature of the interactions among the intake structure, the ice and the hydraulic and meteorological conditions that lead to icing problems is extremely site-specific. The better these parameters are quantified, the more tailored and economical the solution. A defense against these ice forms may be formulated in four arms, the critical of the ice. these parameters are quantified, the more tailored and sconomical the solution. A defense against these ice forms may be formulated in four areas: the origin of the ice, the transportation mechanics of the ice, the accumulation characteristics of the ice, and the form of the ice when it is in the area of influence of the intake. To produce a lake intake structure that minimizes or eliminates icing problems, one may devise an unconstrained or a constrained design. To evaluate solutions to icing problems and/or to supplement incomplete data, a scale-model investigation is recommended. A universal, unconstrained solution would be extremely expensive. The more data available through site monitoring and model studies, the better the problem (and therefore the solution) can be bracketed. This paper provides guidance for developing a site-specific solution.

CR \$3-16 DEVELOPING A MODEL FOR PREDICTING SNOWPACE PARAMETERS AFFECTING VEHI-CLE MOBILITY.

Berger, R.H., May 1983, 26p., ADA-134 878, Refs. p.23-26. 38-878

SNOW COVER EFFECT, TRAFFICABILITY, VEHICLES, SNOW DEPTH, SNOW DENSITY, SNOW ACCUMULATION, ABLATION, TEM-PERATURE EFFECTS, MODELS.

The presence of snow on the ground can impose limitations on the mobility of wheeled and tracked vehicles. Snow depth and density are the two most easily messured snow properties that can be related to mobility over snow. properties that can be related to mobility over snow. Existing models of snowpack accumulation and ablation processes and models of internal snowpack structure were examined to determine if a model of the snowpack can be developed for use in predicting the snow parameters that affect mobility. Simple models, such as temperature index models, do not provide sufficient snowpack details, and the more detailed models required too many measured inputs. Components of the various models were selected from a basis of a snowpack model for predicting anow properties related to mobility over snow. Methods of obtaining the input data for some components are suggested, and areas where more development is needed are described.

COMPARISON OF SEA ICE MODEL RESULTS USING THREE DIFFERENT WIND FORCING

Tucker, W.B., June 1983, 11p., ADA-134 462, 11 refs.

ICE MODELS, SEA ICE, WIND PRESSURE, ICE MECHANICS, ATMOSPHERIC PRESSURE, ICE COVER THICKNESS.

A sea ice model was applied to the Bast Greenland Sea to examine a 60-day ice advance period beginning 1 October 1979. This investigation compares model results using driving geostrophic wind fields derived from three sources. Winds calculated from sea-level pressures obtained from the driving geostrophic wind fields derived from three sources. Winds calculated from see-level pressures obtained from the National Westher Service's operational analysis system resulted in strong velocities concentrated in a narrow band adjacent to the Greenland coast, with moderate velocities elsewhere. The model showed excessive ice transport and thickness build-ups in the coastal region. The extreme pressure reduction procedure that was applied to the terrain-following sigms coordinate system to obtain sea-level pressures. Additional sea-level pressure fields were obtained from an independent optimal interpolation analysis that merged FGGE buoys drifting in the Arctic basin with high latitude land stations and from manual digitization of the NWS hand-analyzed Northern Hemisphere Surface Charts. Modeling results using winds derived from both of these fields agreed favorably. CR 83-18 DETECTION OF CAVITIES UNDER CON-CRETE PAVEMENT

Kovacs, A., et al, July 1983, 41p., ADA-131 851, 10

Morey, R.M. 38-470

CONCRETE PAVEMENTS, CAVITATION, RADAR ECHOES, DETECTION, CRACKING (FRACTURING), PROFILES.

(FRACTURING), PROFILES.

An evaluation of an impulse radar system for detecting cavities under concrete pavement is discussed, and field results are presented. It was found that a dual antenna mode of surveying was ideal for void detection. In this mode one antenna operated in a transceive mode and a second, offset from the first, operated in a receive-only mode. This arrangement allowed a refraction-type profile survey to be performed, which enabled subpavement voids to be easily detected. Field trials were held at Plattubial Air Force Base, where 28 cavities were detected and mapped. Drilling of holes verified that a cavity existed and allowed asvity depth to be measured. The cavities varied from 1.5 in. to 23 in. in depth and were up to 20 ft long. CPB 23-16

CR 83-19 ICE FORCES ON MODEL BRIDGE PIERS. Haynes, F.D., et al, July 1983, 11p., ADA-133 082, 20

Sodhi, D.S., Kato, K., Hirayama, K. 38-395

ICE PRESSURE, ICE LOADS, ICE SOLID INTER-PACE, ICE PUSH, ICE MECHANICS, BRIDGES, PIERS, ICE STRENGTH, MODELS, FLEXURAL STRENGTH, TESTS.

STRENGTH, TESTS.
Small-scale laboratory experiments were conducted on model bridge piers in the CRREL test basin. The experiments were performed by pushing model ice sheets against structures and monitoring the ice forces during the ice/structure interaction. The parameters, varied during the test program, were the geometry of the bridge piers and the velocity, thickness, and flexural strength of the ice. The results are presented in the form of ice forces on aloping and vertical structures with different geometries. During ice sction on aloping structures, a phenomenon of transition of failure mode from bending to crushing was observed as the ice velocity was steadily increased.

CR 83-20 LAND TREATMENT RESEARCH AND DEVEL-OPMENT PROGRAM: SYNTHESIS OF RE-SEARCH RESULTS.

Iskandar, I.K., et al, Aug. 1983, 144p., ADA-134 540, Refs. p.63-124.

Wright, E.A. 38-4419

WASTE TREATMENT, WATER TREATMENT, SANITARY ENGINEERING, LAND RECLAMA-TION, DESIGN CRITERIA, RESEARCH PRO-

JECIS.

The major objective of the Corps of Engineers Land Treatment Research and Development Program was to provide, through research, definitive criteria and procedures to enable the cost-effective and environmentally safe use of land treatment of municipal wastewater. This research included long-term field experiments at different locations within the United States to establish design criteria, laboratory research to understand and solve fundamental problems, and evaluation of existing land treatment systems to decument least-term. understand and solve fundamental problems, and evaluation of existing land treatment systems to document long-term performance. The information gathered from the land treatment research program has been published in more than 240 technical publications on regional planning, site selection, design procedures, mechanisms of wastewater renovation, site management, site monitoring and environmental effects. During the land-treatment program an active technology transfer effort was maintained to transmit research results directly to users. The LTRP clearly demonstrated that land treatment is an attractive alternative to other waste treatment practices. It was also shown that the direct benefits of the program, in terms of increased cost-effectiveness from improved design, were much greater than the program's cost.

CR 83-21 STATISTICAL ASPECTS OF ICE GOUGING ON THE ALASKAN SHELF OF THE BEAUFORT SEA.

Weeks, W.F., et al, Sep. 1983, 34p. + map, ADA-134 428, Refs. p.32-34. Barnes, P.W., Rearic, D.M., Reimnitz, E.

ANALYSIS, BEAUFORT SEA.

ANALYSIS, BEAUFORT SEA.

The statistical characteristics of ice-produced gouges in the sea floor along a 190-km stretch of the Alaskan coast of the Beaufort Sea between Smith Bay and Camden Bay are studied, based on 1500 km of precision fathometry and side-looking sonar records that were obtained between 1972 and 1979 in water depths to 38 m. The probability density function of the gouge depths into the sediment is represented by a simple negative exponential over four decades of gouge frequency. The deepest gouge observed was 3.6 m, from a semple of 20,354 gouges that have depths greater than

or equal to 0.2 m. The dominant gouge orientations are usually unimodal and reasonably clustered, with the most frequent alignments roughly parallel to the seneral trend of the coastline. The value of the mean number of gouges (deeper than 0.2 m) per kilometer measured normal to the trend of the gouges, varies from 0.2 for protected lagoons to 80 in water between 20 and 38 m deep in unprotected offshore regions. The distribution of the spacings between gouges as measured along a sampling track is a negative exponential. The form of the frequency distribution of the mean number of gouges varies with water depth and is exponential for lagoons and shallow offshore areas, positively skewed for 10 to 20 m depths off the barrier islands, and near-normal for deeper water. As a Poisson distribution gives a reasonable fit to the mean number of gouges distributions for all water depths, it is suggested that gouging can be taken as approximating a Poisson process in both space and time. The distributions of the largest values per kilometer of gouge depths, gouge widths, and heights of the lateral embankments of sediments plowed from the gouges are also investigated. Limited data on gouging rates give an average of 5 gouges per kilometer per year. Examples are given of the application of the data set to hypothetical design problems associated with the production of oil from areas in the Alaskan portion of the Beaufort Ses.

TRANSPORT OF WATER IN FROZEN SOIL. 1. EXPERIMENTAL DETERMINATION OF SOIL-WATER DIFFUSIVITY UNDER ISOTHERMAL CONDITIONS.

Nakano, Y., et al, Aug. 1983, 8p., ADA-135 419, For another source see 37-4218. 13 refs.

FROZEN GROUND MECHANICS, SOIL WATER MIGRATION, FROST HEAVE, UNFROZEN WATER CONTENT, SOIL MECHANICS, WATER TRANSPORT, ANALYSIS (MATHEMATICS), EXPERIMENTATION.

A new experimental method for measuring the soil-water diffusivity of frozen soil under isothermal conditions is introduced. The theoretical justification of the method is presented and the feasibility of the method is demonstrated by experiments conducted using marine-deposited clay. The measured values of the soil-water disavity are found comparable to reported experimental data.

STRESS MEASUREMENTS IN ICE. Cox, G.F.N., et al, Aug. 1983, 31p., ADA-133 906, 29

Johnson, J.B. 38-4463

ICE PHYSICS, STRESSES, LOADS (FORCES), ICE CREEP, ICE BLASTICITY, MEASURING INSTRUMENTS, ANALYSIS (MATHEMATICS),

he problems associated with measuring stresses in ice are releviewed. Theory and laboratory test results are then resented for a stiff cylindrical sensor made of steel that presented for a stiff cylindrical sensor made of steel that is designed to measure ice stresses in a biaxial stress field. Loading tests on freshwater and saline ice blocks containing the biaxial ice stress sensor indicate that the sensor has a resolution of 20 kPa and an accuracy of better than 15% under a variety of uniaxial and biaxial loading conditions. Principal stress directions can also be determined within 5 deg. The biaxial ice stress sensor is not significantly affected by variations in the ice elastic modulus, ice creep or differential thermal expansion between the ice and guage. The sensor also has a low temperature sensitivity (5 kPa degC).

SOIL MICROBIOLOGY, ROOTS, DAMAGE.
Secondary recovery of oil at Prubho Bay, Alaska, will involve transporting large quantities of seawater in elevated pipelines across tundra for injection into oil-bearing rock strata. The possibility of a pipeline rupture raises questions concerning the effects of seawater on tundra vegetation and soils. To evaluate the relative sensitivities of different plant communities to seawater, eight sites representing the range of vegetation types along the pipeline route were reasted with single, saturating applications of seawater during the summer of 1980. Live (green) bryophyte cover was markedly reduced in the moist experimental sites in 1981. Bryophytes in all but one of the wet-site experimental plots were apparently unaffected by the seawater treatment. Two species of foliose lichers treated with seawater showed marked deterioration in 1981. All other lichen taxa were apparently unaffected by the seawater treatment. On spill sites, microbial-related soil respiration and hydrolysis of cellulose and organic phosphorus were significantly reduced, as were soil

enzymes and viable microbial biomass, for up to one year after treatment. Ectomycorrhizal roots of Salix on the treated plots showed a significant reduction in viable biomass, number of mycerrhizal roots. of mycorrhizal roots, and respiration rates of the

URAL STRENGIH, TESTS.

lee action on two cylindrical and conical structures, located side by side, has been investigated in a small-scale experimental study to determine the interference effects on the ice forces generated during ice-structure interaction. The proximity of the two structures changes the mode of ice failure, the magnitude and direction of ice forces on the individual structure, and the dominant frequency of ice force variations. Interference effects were determined by comparing the experimental results of tests at different structure spacings.

CR 83-26
MECHANICAL ICE RELEASE PROCESSES.
PROM HIGH-SPEED 1 SELF-SHEDDING FROM HIGH-SPEED RO-TORS.

Itagaki, K., Oct. 1983, 8p., ADA-135 369, 19 refs. 38-4465

ICE REMOVAL, PROPELLERS, ICING, ICE AC-CRETION, SUPERCOOLED FOG, ICE FORMA-TION, ICE ADHESION, ICE STRENGTH, ICE CONTROL, TENSILE PROPERTIES, ANALYSIS (MATHEMATICS).

(MATRIBMATICS).

Les accreted on high-speed rotors operating in supercooled fog can be thrown off by centrifugal force, creating severe unbalance and dangerous projectiles. A simple force balance analysis indicates that the strength of accreted ice and its adhesive strength can be obtained by measuring the thickness of the accretion, the location of the separation, the rotor speed and the density. Such an analysis was applied to field and laboratory observations of self-shedding events. The results agree reasonably well with other observations.

DRIVING TRACTION ON ICE WITH ALL-SEA-SON AND MUD-AND-SNOW RADIAL TIRES. Blaisdell, G.L., Nov. 1983, 22p., ADA-136 115, 9 refs. 38-2555

RUBBER ICE FRICTION, TRACTION, TIRES, RUBBER SNOW FRICTION, ICE TEMPERA-TURE, ADHESION, DESIGN.

TURE, ADHESION, DESIGN.

This study reports on a comparison of the driving traction performance on ice of a selected group of all-season radial tires with mud-and-snow radial tires. In addition to performance variation due to tread design, the effects of tire inflation pressure and ice temperature are explored. The results indicate that no significant tractive advantage on ice can be attributed to tread design. The contribution of tire tread to traction on ice is completely overshadowed by adhesion between the ice and the compound which makes up the tire's contact surface. Based on adhesion, a slight favoring of all-season tires is found. Increasing ice temperature generally decreased the tractive capability of a specific tire. For several tires, however, the opposite was true. Reduced inflation pressure also caused a slight decrease in the tractive performance parameters calculated.

CR 83-28 LONG-TERM PLANT PERSISTENCE AND RES-TORATION OF ACIDIC DREDGE SOILS WITH SEWAGE SLUDGE AND LIME.
Palazzo, A.J., Dec. 1983, 11p., ADA-137 451, 31 refs.

38-1658

DREDGING, SOIL CHEMISTRY, SEWAGE TREATMENT, REVEGETATION, LIMING, SLUDGES, LAND RECLAMATION, GRASSES. SLUDGES, LAND RECLAMATION, GRASSES. A field study was conducted to determine whether sewage aludge and lime could be useful as soil amendments on acidic (pH 2.4) and infertile dredged spoils and to evaluate grasses that may be suitable for restoring acidic dredged spoils. Applications of dolomitic limestone in combination with sewage sludge or commercial fertilizer and topsoil mythorous soil fertility and produced a better overall growth environment at the site. Metal concentrations resulting from sludge applications increased but not to excessive levels. Movement of metals below the 20-cm depth was noted for the extractible forms of zinc, copper and nickel. A total of 29 grass treatments, containing grasses seeded alone or in combinations and receiving the sludge/lime treatment, were evaluated over a seven-year period, and selected grasses were analyzed for mineral composition. All grass species showed good establishment on the amended acidic spoil. CR 83-29 OF PERENNIALLY FROZEN STREAMBANKS

Lawson, D.B., Dec. 1983, 22p., ADA-138 410, Refs.

p.14-17. 38-4466

SHORE EROSION, PERMAPROST THERMAL PROPERTIES, BANKS (WATERWAYS), FROZ-EN GROUND STRENGTH, SOIL EROSION, STABILITY, GULLIES, SHORELINE MODIFICA-TION, STREAMS, TEMPERATURE EFFECTS, HYDRAULICS.

review indicated that the effects of perm nk erodibility and stability are not yet under because systematic and quantitative measurements are serious-ly lacking. Consequently, general controversy exists as to whether perennially frozen ground inhibits lateral eroin and bankline recession, or whether it increases bank recession and banktine recession, or whether it increases bank recession rates. Perennially frozen streambanks erode because of modification of the bank's thermal regime by exposure to air and water, and because of various erosional processes. Pactors that determine rates and locations of erosion include physical, thermal and structural properties of bank sediments, stream hydraulics and climate. Thermal and physical modification of streambanks may also induce accelerated erosion within permafrost terrain removed from the immediate river environment. Bankline or bluffline recession rates are highly variable, remains from less than 1 m/west to very 30 m/year environment. Bankine or olumine recession rates are again, variable, ranging from less than 1 m/year to over 30 m/year and, exceptionally, to over 60 m/year. Long-term observations of the physical and thermal erosion processes and systematic ground surveys and measurements of bankline-biuffline recession rates are needed.

CR 83-30

ICE SHEET RETENTION STRUCTURES. Perham, R.E., Dec. 1983, 33p., ADA-138 030, Refs.

p.27-29. 38-4467

ICE CONTROL, ICE BOOMS, STABILIZATION, ICE SHEETS, ICE COVER, FRAZIL ICE. Ice sheets are formed and retained in several ways in nature, and an understanding of these factors is needed before most

structures can be successfully applied. Many ice sheet retention structures float and are somewhat flexible; others are fixed and rigid or semirigid. An example of the former is the Lake Brie ice boom and of the latter, the former is the Lake Erie ice boom and of the latter, the Montreal ice control structure. Ice sheet retention technology is changing. The use of timber cribs is gradually but not totally giving way to sheet steel pilings and concrete cells. New structures and applications are being tried but with caution. Ice-hydraulic analyses are helpful in predicting the effects of structures and channel modifications on ice cover formation and retention. Often, varying the flow rate in a particular system at the proper time will make the difference between whether a structure will or will not retain ice. The structure, however, invariably adds reliability to the sheet ice retention process.

CR 83-31 MECHANICS OF ICE JAM FORMATION IN RIVERS.

Ackermann, N.L., et al, Dec. 1983, 14p., ADA-138 371, For another version see 36-3281. 12 refs. Shen, H.T.

ICE JAMS, ICE FORMATION, ICE MECHANICS, RIVER ICE, RIVER FLOW, HYDRAULICS, ICE CROSSINGS, COMPUTER PROGRAMS, MATHEMATICAL MODELS.

A mathematical model is described that is used to determine the maximum ice conveyance capacity of a river channel. Based upon this model, computer programs were developed that enable the ice discharge to be calculated for steady-state flow conditions. For rivers that have uniform flow, the maximum ice-conveying capacity can be described with a simple function expressed in terms of the size of the ice fragments, channel geometry, and the flow of water in the river. For nonuniform flows, the computer program determines the elevation profile of the surface layer in addition to other flow characteristics, such as the velocity and surface concentration of the ice fragments. The location along this surface profile where the ice conveyance capacity becomes less than the upstream supply is determined and is considered to be the position where a surface ice jam or ice bridge will be formed. A mathematical model is described that is used to determine to be the positi will be formed.

ICE FORCE MEASUREMENTS ON A BRIDGE PIER IN THE OTTAUQUECHEE RIVER, VER-MON

ICE LOADS, ICE PLOES, PIERS, BRIDGES, ICE PRESSURE, RIVER ICE, WATER LEVEL, ICE STRENGTH, ICE MECHANICS.

lee forces on a bridge pler in the Ottauquechee River, in Quechee, Vermont, were measured by installing four panels—each capable of measuring forces in the normal and tangential direction—on both sides of a vertical V-shaped pier nose. The measured forces are presented for a short period during an ice run. After the ice run, the thickness and sizes

of the ice floes were measured and the compressive strength of the ice was determined in the laboratory from the ice samples collected along the river banks. The water level measurements made at several locations along the river are also presented for the period of the ice run.

THERMODYNAMIC MODEL OF CREEP AT CONSTANT STRESSES AND CONSTANT STRAIN RATES.

Fish, A.M., Dec. 1983, 18p., ADA-139 883, Refs. p.16-18. 38-4470

SOIL CREEP, FROZEN GROUND THERMODY-NAMICS, FROZEN GROUND MECHANICS, ICE MECHANICS, STRESSES, STRAINS, RHEOLO-GY, MATHEMATICAL MODELS.

A thermodynamic model has been developed that for the first time describes the entire creep process, including primary, secondary, and tertiary creep, and failure for both constant stress (CS) tests and constant strain rate (CSR) tests, in the form of a unified constitutive equation and unified failure criteria. Deformation and failure are considered as a single criteria. Deformation and failure are considered as a single thermoactivated process in which the dominant role belongs to the change of entropy. Failure occurs when the entropy change is zero. At the moment the strain rates in CS tests reach the minima and stress in CSR tests reaches the maximum (peak) values. Families of creep and stress-strain curves, obtained from uniaxial compression CS and CSR tests of frozen soil, respectively (both presented in dimensionless coordinates), are plotted as straight lines and are superposed, confirming the unity of the deformation and failure process and the validity of the model. A method is developed for determining the parameters of the model, so that creep deformation and the stress-strain relationship of ductile materials such as soils can be predicted based upon information obtained from either type of test.

IN-SITU BUILDING R-VALUE TOWARD MEASUREMENT.

Flanders, S.N., et al, Jan. 1984, 13p., ADA-139 917,

Marshall S.I.

THERMAL CONDUCTIVITY, BUILDINGS, THERMAL INSULATION, WALLS, HEAT FLUX, TEMPERATURE MEASUREMENT, INFRARED PHOTOGRAPHY, ACCURACY

PHOTOGRAPHY, ACCURACY.

A technique for measuring the thermal resistance (R-value) of large areas of building envelope is under development temploys infrared thermography to locate radiant temperature extremes on a building surface and to provide a map of normalized temperature values for interpolation between locations. Contact thermal sensors (thermocouples for temperature and thermopiles for heat flow) are used to calculate the R-value at specific locations by summing the output from each sensor until the ratio between temperature difference from inside to outside surface and heat flow converges to a constant value. R-value measurements of a wood frame insulated wall were within 13% of the expected theoretical value. Similar measurements of a masonry wall were 31 and 43% less than expected. Experimentation demonstrated that a large ratio between temperature difference was the single most important variable affecting accuracy and speed of convergence. Thermal guards around heat flow sensors were of little value, according to both experimentation and computer simulation. Attempts to match the absorptivity of sensors with their surroundings may have been insufficent to diminish about 10% of the remaining error in measurement. Lateral heat flow and convection may have been significant problems for accuracy in the masonry construction. Currently, an investigator cannot rely on the literature for guidance in assessing the limitations on accuracy for in-situ building R-value measurement.

ELECTROMAGNETIC PROPERTIES OF SEA ICE.

Morey, R.M., et al, Jan. 1984, 32p., ADA-140 330, 26 refa

Kovaca, A., Cox, G.F.N.

38-4472 ICE ELECTRICAL PROPERTIES, SEA ICE ELECTROMAGNETIC PROPERTIES, DIELEC-TRIC PROPERTIES, ELECTRICAL RESISTIVITY, ICE SPECTROSCOPY, ICE CRYSTAL STRUC-TURE, ANISOTROPY, BRINES.

TURE, ANISOTROPY, BRINES.
Investigations of the in situ complex dielectric constant of sea ice were made using time-domain spectroscopy. It was found that (1) for sea ice with a preferred horizontal crystal c-axis alignment, the anisotropy or polarizing properties of the ice increased with depth, (2) brine inclusion conductivity increased with decreasing temperature down to about -8. (3 twhich point the conductivity decreased with decreasing temperature of the complex dielectric constant is strongly dependent upon brine volume but less dependent upon the brine inclusion orientation, (5) the tengendary part of the complex dielectric constant was strongly dependent upon brine volume. Because the electromagnetic (EM) properties of sea ice are dependent upon the physical state of the ice, which is continually changing,

it appears that only trends in the relationships between the EM properties of natural sea ice and its brine volume and brine inclusion microstructure can be established.

CTR 84-03 MODEL TESTS ON TWO MODELS OF WIGH 140-POOT ICEBREAKER.

ICEBREAKERS, ICE COVER STRENGTH, ICE CONDITIONS, ICE BREAKING, UREA, DOPED ICE MODELS.

The results of resistance tests in level ice and broken ice channels are presented for two models of the WTGB 140-ft icebreaker at scales of 1:10 and 1:24, respectively. No scale effect on the resistance in level ice could be detected between the two models. From the test results an empirical predictor equation for the full scale ice resistance is derived. Predicted resistance is compared against, and found to be 25 to 40% larger than, available full-scale values estimated from thrust measurements during full-scale trials of the Great Lakes icebreaker Katmai Bas

CR 84-04

EFFECTIVENESS AND INFLUENCES OF THE NAVIGATION ICE BOOMS ON THE ST.

Perham, R.E., Jan. 1984, 12p., ADA-139 908, 8 refs. 38-4474

ICE NAVIGATION, ICE BOOMS, RIVER ICE, ICE BREAKING, ICE CONTROL, ICE BREAKUP. ICE MECHANICS, ICE COVER THICKNESS.

Ice problems developed in the Sault Ste. Marie, Michigan, portion of the St. Marys River because of winter navigation. Passing ships and natural influences moved ice from Soo Harbor into Little Rapids Cut in sufficient quantities to Harbor into Little Rapids Cut in sumicient quantities to jam, cause high water in the harbor, and prevent further ship passage. After physical model and engineering studies, two ice booms with a total span of 1375 ft (419 m) with a 250-ft (76-m) navigation opening between were installed at the head of Little Rapids Cut in 1975. A modest field study program on the booms was conducted for the ensuing four winters to determine ice and boom interaction and the effects of ship passages on the system. Excess ensuing four winters to determine ice and boom interaction and the effects of ship passages on the system. Forces on some anchors were recorded and supplemental data were taken by local personnel. Several reports have been written about the booms' early operations. This paper presents a four-year summary of the main effects of the boom on left of the boom on the four winter sessons, the small quantities of ice lost over and between the booms were manageable. Ships usually passed through the boom without influencing the boom force levels, but at times they brought about large changes. One boom needed strengthening, and artificial islands were added for upstream ice stability. Coast Guard icebreakers were also a necessary part of winter navigation in this area.

MORPHOLOGY AND ECOLOGY OF DIATOMS IN SEA ICE FROM THE WEDDELL SEA Clarke, D.B., et al, Feb. 1984, 41p., ADA-141 994,

SIFICATIONS, WEDDELL SEA.

Diatom species composition and relative abundances were determined for ice cores obtained from Weddell Sea pack ice during the October-November 1981 Weddell Polynya expedition (WEPOLEX). Ice thickness and salinity indicate that the ice was less than one year old. The predominant ice type (70%) was frazil, which has the capacity to mechanically incorporate biological material through nucleation and scavenging.

Diatoms were found throughout the length of the cores. Species showed down-core fluctuations in ice type. Pennate forms were more abundant than centrica, the average ratio being 16:1. Diatom frustules with intact crasmic material were more abundant (50 million cells/liter). rage ratio being 16:1. material were more the average ratio being 16:1. Diatom frustules with must organic material were more abundant (50 million cells/liter). Differences in species abundances are attributed initially to incorporation of algal cells from a temporally changing water column and subsequently to diatom reproduction within the ice. Scanning electron micrographs illustrating the morphologic characteristics of the predominant species are includ-

CD SAME AEROSOL GROWTH IN A COLD ENVIRON-

Yen, Y.-C., Feb. 1984, 21p., ADA-139 907, 4 refs. 38-4475

ABROSOLS, GROWTH, HEAT TRANSFER, MASS TRANSFER, VAPOR DIFFUSION, COLD WEATHER TESTS, ANALYSIS (MATHEMATICS), DROPS (LIQUIDS), TEMPERATURE EF-ICS), D FECTS.

An expression relating aerosol growth to cold environmental conditions was developed. This was accomplished by solving the diffusion equation with the method of Laplace transformation. The series solution was expressed in terms of the ratio of vapor density over droplet surface to droplet density, ratio of environmental vapor density at time zero to vapor

sity over droplet surface, and ratio of product of diffusion fficient and time to square of initial radius of condensation censity over dropest surface, sno result or product or diminsion coefficient and time to square of initial radius of condensation nucleus. To take into account the variation of the vapor density over the surface of an acidic condensation nucleus due to the continuous dilution of the droplet, the solution was obtained by assuming various levels of constant vapor

CR 84-07 FORCE DISTRIBUTION IN A FRAGMENTED ICE COVER

Stewart, D.M., et al, Mar. 1984, 16p., ADA-142 100,

Daly, S.F. 38-4476

ICE FLOES, SHEAR STRESS, FLOATING ICE, LOADS (FORCES), ICE BOOMS, ICE LOADS, RIVER ICE, ICE COVER THICKNESS, SHORES, EXPERIMENTATION.

Experiments were conducted in CRREL's refrigerated flume facility to examine the two-dimensional force distribution of a floating, fragmented ice cover restrained by a boom in a simulated river channel. To determine the force distribution, a vertically walled channel, instrumented for m a simulate inver channel. To determine the force distribution, a vertically walled channel, instrumented for measuring normal and tangential forces, and an instrumented for measuring boom were installed in a 40.0 by 1.3-m flume. Two sizes of polyethylene blocks and two similar sizes of freshwater ice blocks were tested using water velocities ranging from 10 to 30 cm/s. The forces measured at the instrumented boom leveled off with increasing cover length. The contribution of the increasing shear forces developed along the shorelines to this leveling off in the data was clearly evident. The shear coefficients of the polyethylene blocks averaged 0.43, and the freshwater ice averaged 0.044. The normal force measured along the instrumented shoreline could not be related simply by a K coefficient to the longitudinal force; another expression was required, with a term being a function of the cover thickness and independent of the undercover shear stress or cover length. By adding this term, good agreement was then found between the measured and predicted values of the boom forces and the shoreline normal and shear forces.

FLOES, STATISTICAL ANALYSIS.

This report presents the results of the first phase of a test program designed to obtain a comprehensive understanding of the mechanical properties of multi-year sea ice from the Alaakan Beaufort Sea. In Phase I, 222 constant-strain-rate uniaxial compression tests were performed on ice samples from ten multi-year pressure ridges to examine the magnitude and variation of ice strength within and between pressure ridges. A limited number of constant-strain-rate compression and tension tests, constant-load compression tests, and conventional triaxial tests were also performed on ice samples from a multi-year floe to provide preliminary data for developing ice yield criteria and constitutive laws for multi-year sea ice. Data are presented on the strength, failure strain, and modulus of multi-year sea ice under different loading conditions. The statistical variation of ice strength within and between pressure ridges is examined, as well as the effects of ice temperature, porosity, structure, strain rate to of ice temperature, porosity, structure, strain rat confining pressure on the mechanical properties of multi sea ice.

CR 84-10 MODELING TWO-DIMENSIONAL FREEZING USING TRANSFINITE MAPPINGS AND A MOVING-MESH FINITE ELEMENT TECH-NIQUE

Albert, M.R., May 1984, 45p., ADA-144 131, 29 refs. 39-383

FREEZING, PHASE TRANSFORMATIONS, HEAT TRANSFER, BOUNDARY VALUE PROB-LEMS, MATHEMATICAL MODELS, LATENT HEAT.

HEAT.

Preezing phase change problems in conduction heat transfer represent a set of moving boundary problems for which much interest currently exists. In the work presented here, two-dimensional freezing is modeled by incorporating the use of transfinite mappings with a moving-mesh finite element technique. The use of transfinite mapping in governing interior mesh motion is shown to provide very acceptable results and is demonstrated to be the most efficient. acceptable results and is demonstrated to be the most efficient general computational technique used to date. The model developed is capable of using either Cartesian or (r,z) cylindrical coordinates. Both frozen and unfrozen phases may be modeled when conduction governs behavior in both. In the case of freezing of a fluid as it flows through a pipe the usefulness of always having the phase boundary coincident with element boundaries is demonstrated. Results of the model are shown to compare well with analytical and experimental results. A von Neumann stability analysis is performed for the numerical solution and tends to support the observation that the occurrence of a high Peclet number in the moving-mesh model of heat conduction may produce distortions of the numerical solution.

SEA ICE DATA BUOYS IN THE WEDDELL SEA. Ackley, S.F., et al, May 1984, 18p., ADA-144 953, 6

Holt, B.T. 39-384

SEA ICE DISTRIBUTION, PACK ICE, DRIFT, WEATHER OBSERVATIONS, DRIFT STATIONS, ATMOSPHERIC PRESSURE, AIR TEMPERATURE, ANTARCTICA—WEDDELL SEA.

Data obtained from two sets of data buoys either air-dropped or deployed by ship onto the Weddell Sea pack ice during the period from Dec 1978 to Nov 1980 are presented. The buoy data include position, pressure and temperature information and to date represent the most complete combined The buoy data include position, pressure and temperature information and to date represent the most complete combined weather and pack ice drift records for the ice-covered southern ocean regions. The buoys tended to drift north initially and then to turn east generally between initiales 62 S and 64 S. Buoy 1433 turned east farther south at approximately 67 S but at about the same time as buoy 0527, implying that the westerly wind belt was farther south than usual in 1979. The range of air pressures—from about 950 mb to about 1020 mb—is typical of the circumpolar low pressure trough in the Southern Hemisphere. All buoys were equipped with an internal or compartment temperature sensor. The buoys also contained an enternal air temperature sensor in a ventilated, shielded can at 1—nheight. Although differences of 10 C or more between recorded air and compartment temperatures are common, the correlation between the two measured temperatures is generally very good. The compartment temperatures is generally very good. The compartment temperatures are the found that subtracting 3 C from the average daily compartment temperature for any given day. This technique can be used to construct average daily air temperature records for the 1979 buoys which only contained the internal or compartment temperature sensor. aperature sensor.

CR 84-12 ICING RATE ON STATIONARY STRUCTURES UNDER MARINE CONDITIONS. Itagaki, K., June 1984, 9p., ADA-145 797, 7 refs. 39-385

ICING, OFFSHORE STRUCTURES, ICE FORMATION, OFFSHORE DRILLING, SHIP ICING, SEA SPRAY, WIND VELOCITY, ANALYSIS (MATH-EMATICS)

The rate of ice accumulation on stationary structures was calculated using published data. The results were compared with icing measured on board ships. Although the general trend of this calculation indicated parallelism with the coboard measurements, the measured ice accumulation rate on ships needed a 5 to 8 m/s higher windspeed to correspond with the calculated rate for stationary structures.

CR 84-13

NITROGEN REMOVAL IN WASTEWATER PONDS. Reed, S.C., June 1984, 26p., ADA-144 971, 26 refs.

WASTE TREATMENT, ICE COVER EFFECT, WATER TREATMENT, SANITARY ENGINEER-ING, PONDS, CHEMICAL ANALYSIS, MATH-EMATICAL MODELS.

Nitrogen removal from wastewater can be required in a number of situations, and many military facilities have been or will be retrofitted for this purpose. Treatment lagoons and holding or storage ponds are a common treatment method or a common component in many systems. Qualitative observations over several decades document nitrogen losses

from these systems due to a variety of possible biochemical interactions. This analysis is based on an extensive body of quantitative data recently published by the U.S. EPA. A mathematical model was developed and validated that indicated that nitrogen removal from pond systems is dependent on pH, temperature, and detention time. The specific biochemical factors could not be isolated, but the analysis suggests that volatilization of ammonia is the major pathway for nitrogen loss. The model can be used as a design equation for new facilities, for retrofits, and for land treatment systems with storage ponds, since nitrogen is a critical design perameter in these cases.

PLANT TISSUES, TEMPERATURE EFFECTS,
UNFROZEN WATER CONTENT, COLD TOLERANCE, LOW TEMPERATURE TESTS, GROWTH,
DAMAGE, NUCLAR MAGNETIC RESONANCE, AQUATIC PLANTS.

Two laboratory studies were performed to investigate the effects of low temperatures on the equatic plant Ceratophyllum dimensum L. Whole plants were subjected to low-temperature treatments of +4, 0 and -6C for 48 hours, and regrowth dimersiant. Whole plants were subjected to low-temperature treatments of +4,0 and -6C for 48 hours, and regrowth
was compared to an untreated control. The control and
+4C-treated plants gained weight, while visible injury and
reductions in plant biomass were noted 30 days after treatment
at the two lower temperatures. The -6C treatment killed
the plants, while the OC treatment injured them to some
degree. In another phase of this study, nuclear magnetic
resonance (NMR) analysis of plant buds, leaves and stems
showed that lowering temperatures caused the plants' unifrozen
water content to drop rapidly as the temperature approached
-5C, then slowly as temperatures approached -13C. From
-13C to -22C there was little change in unfrozen water
content. The results show that toe in this plant causes
injury that affects subsequent regrowth; temperatures of 6C or below can actually kill them. This killing temperature
was also near the point where frozen water content increased
only slightly with lower temperatures. NMR analysis could
be one way of determining plant tolerance to cold. It
appears from this study that this weedy species is susceptible
to low-temperature injury, and subjecting this plant to cold
may be a promising method of weed control in northern
lakes.

BASELINE ACIDITY OF ANCIENT PRECIPITA-TION FROM THE SOUTH POLE.

Cragin, J.H., et al, June 1984, 7p., ADA-145 007, 33

BN-SCOTT STATION.

Measurements of meltwater pH from annual layers of South Pole firm and ice samples ranging in age from 40 to 2000 years B.P. show that precipitation at this remote site has a higher natural acidity than that expected from atmospheric equilibrium with CO2. The average pH of deserated (CO2-free) samples was 5.64, while sir-equilibrated samples averaged 5.37, a pH that is about a factor of two more acidic than the expected background pH of 5.65. The observed "excess" acidity can be accounted for actual SOC and SO use expected userground pri or 3.63. The observed "excess" scidity can be accounted for by natural SO4 and NO3 lon levels in the samples probably originating from non-anthropogenic H2SO4 and HNO3. Because of the presence of these naturally occurring acids in South Pole precipitation, a pH of 5.4 is considered a more representative baseline reference pH for acid precipitation studies.

EFFECTS OF SOLUBLE SALTS ON THE UN-FROZEN WATER CONTENTS OF THE LANZ-HOU, P.R.C., SILT.

Tice, A.R., et al, June 1984, 18p., ADA-152 825, 24

Zhu, Y., Oliphant, J.L. 39-2916

JOURNAL WATER CONTENT, SALINE SOILS, LOESS, SOIL WATER, SOLUBILITY, TEMPERATURE EFFECTS, ELECTRICAL

Phase composition curves are presented for a typical saline silt from Lanzhou, P.R.C., and compared to some silts from Alaska. The unfrozen water content of the Chinese silts much higher than that of the Alaskan silts due to the large amount of soluble salts present in the silts from China, which are not present in silt from interior Alaska. When the salt is removed, the unfrozen water content is then similar for both the Chinese and Alaskan silt. Here we introduce a technique for correcting the unfrozen water content of partially frozen soils due to high sait concentrations. We calculate the equivalent moisity of the saits in the unfrozen water at various temperatures from a measurement of the electrical conductivity of the extract from saturated

PULSE TRANSMISSION THROUGH FROZEN SILT.

PROZEN GROUND PHYSICS, RADIO WAVES, WAVE PROPAGATION, PERMAFROST SICS, RADAR, TEMPERATURE EFFECTS.

SICS, RADAR, TEMPERATURE EFFECTS.

VHF-band radiowave short pulses were transmitted within the permafrost tunnel at Fox, Alaska, over distances between 2.2 and 10.5 m. The propagation medium was a frozen silt containing both disseminated and massive lee with temperatures varying from -7C near the transmitter to probably -3C near the center of the tunnel overburden. The short pulses underweat practically no dispersion in the coldest zones but did disperse and refract through the warmer overburden, as suggested by calculations of the effective dielectric constant. Most significantly the measured frequency content decreased as the effective dielectric constant increased. The results indicate that deep cross-borehole miss transmistent occressed as the execute desectors constant increased. The results indicate that deep, cross-borehole pulse transmissions over distances greater than 10 m might be possible, especially when the ground is no warmer than -4C. The information thus gained could be used for identifying major subsurface variations, including ground ice features.

FRAZIL ICE, ICE FORMATION, HEAT TRANS-FER, PARTICLE SIZE DISTRIBUTION, MATH-EMATICAL MODELS, TESTS, TURBULENT FLOW, WATER TEMPERATURE, COMPUTER PROGRAMS, SUPERCOOLING.

PROGRAMS, SUPERCOOLING.

This report investigates the influences of turbulence and water temperature on frazil ice formation. The rate and the quantity of frazil ice formed in a specified volume of supercooled water increase with both increasing turbulence intensity and decreasing water temperature. The influence of turbulence intensity on the rate of frazil ice formation, however, is more pronounced for larger initial supercooling. The turbulence characteristics of a flow affect the rate of frazil ice formation by governing the temperature to which the flow can be supercooled by influencing heat transfer from the frazil ice to surrounding water, and by promoting collision nucleation, particle and floc rupture and increasing the number of nucleation sites.

Larger frazil ice particles and flor rupture and increasing the number of nucleation sites.

Larger frazil ice particles and flow affect the rate of frazil ice particles greater than their thickness. Particle size generally decreased with increasing turbulence intensity.

The report rate of frazil ice formation of liquid water to ice. Experiments conducted in a turbulence jar with a heated, vertically oscillating grid served both to guide and to calibrate the analytical model as well as to afford insights into frazil ice formation.

ICE FORMATION, RIVER ICE, WATER TEM-PERATURE, PREEZEUP, LONG RANGE PORE-CASTING, COMPUTER PROGRAMS.

CASTING, COMPUTER PROGRAMS.

In this study a method for making long-range forecasts of freeze-up dates in rivers is developed. The method requires the initial water temperature is an upstream station, the long-range air temperature forecast, the predicted mean flow velocity in the river reach, and water temperature response parameters.

The water temperature response parameters can be either estimated from the surface heat exchange coefficient and the average flow depth or determined empirically from recorded air and water temperature data. The method is applied to the St. Lawrence River between Kingston, Ontario, and Massena, New York, and is shown to be capable of accurately forecasting freeze-up.

CHANGE IN ORIENTATION OF ARTILLERY-DELIVERED ANTI-TANK MINES IN SNOW. Bigl, S.R., Aug. 1984, 20p., ADA-090 946, 5 refs. 39-2917

MILITARY OPERATION, TANKS (COMBAT VEHICLES), SNOW COVER EFFECT, ORIENTA-TION, TEMPERATURE EFFECTS, TESTS.

TION, TEMPERATURE EFFECTS, TESTS.

The Remote Anti-Armor Mine System (RAAMS) employs acatterable mines that are delivered by ejection from a projectile during flight. A problem with delivery of RAAMS mines in snow arises because a percentage of them are equipped with an anti-disturbance mechanism. The natural disturbance or tilting of the mines while melting into the snow on a warm or sunny day may cause them to detonate. Five tests lasting 3 hours to 5 days were conducted at CRREL to study change in orientation of RAAMS mines after landing in snow. Mines were set in the snow at

various repose angles and their orientations were recorded periodically. The tests indicated that a critical angle of approximately 65 deg from horizontal divides the settlement patterns of the mines. Those with initial repose angles below 65 deg will tend towards 0 deg, while more steeply dipping mines will most often come to rest in a vertical position. Angular change rates during midday hours (0900-1500) ranged from 0 deg to 10 deg per hour. On sunny dates with secretaring temperatures. ranged from 0 deg to 10 deg per hour. On sunny days with near-freezing temperatures, most mines had a total one-day change of 10 deg to 25 deg. From these tests, it appears that many of the mines would have detonated if they had been equipped with an anti-disturbance mechanism.

CR \$4-21 IMPACT OF DREDGING ON WATER QUALITY AT KEWAUNEE HARBOR, WISCONSIN. Iskandar, I.K., et al, Aug. 1984, 16p., ADA-148 321,

DREDGING, SEDIMENTS, WASTE DISPOSAL, WATER POLLUTION, LACUSTRINE DEPOSITS, WATER CHEMISTRY, PORTS, UNITED STATES WISCONSIN--KEWAUNEE

Six sediments and four water samples were collected from Kewamee, Wisconsin, in 1981, prior to dredging of this Lake Michigan harbor: A modified elutrate text was used to estimate potential impact on water quality upon harbor dredging and disposal of the sediments in a confined facility. to estimate potential impact on water quality upon harbor dredging and disposal of the sediments in a confined facility. The modification of the test included a comparison between containment release under serated vs unserated conditions and filtered vs unfiltered elutrates. Statistical analysis showed that the differences in the chemical characteristics between the filtered and unfiltered samples were significant for soluble reactive P and all the tested metals except Cu. Ni, Fe, Mm) and soluble reactive P will be released to the water if the effluent is not filtered. Under aerated conditions, COD in both the filtered and unfiltered samples was higher than under unserated conditions. In contrast, total organic carbon was much higher under the unserated condition than under serated conditions. The study concluded that sediment and contuninant releases from the confined disposal facility (CDF) to the harbor water were less than those from the Kewaunee River input. Also, retention of effluent in the CDF for about four days decreased the suspended solids in the effuent to about 40 to 50 mg/L, which is similar to the concentration in the lake water. The use of sand filters should not be for routine operation but rather for emergency cases when there is not enough time for effluent retention in this CDF. but rather for emergency cases when there is not enough time for effluent retention in this CDF.

REGIONAL AND SEASONAL VARIATIONS IN SNOW-COVER DENSITY IN THE U.S.S.R.

SNOW COVER DISTRIBUTION, SNOW DENSITY, SNOW SURVEYS, SNOW DEPTH, TOPOGRAPHIC EFFECTS, GEOGRAPHY, SEASONAL VARIATIONS, WIND VELOCITY, FOREST VARIATIONS, WIND VE CANOPY, MAPPING, USSR.

CANOPY, MAPPING, USSR.
Regional and seasonal variations in snow-cover density (SCD) in the U.S.S.R. were determined through the analysis of data obtained from all available Soviet literature. A relation-hip found between observed winter wind speeds and SCD values recorded from November through March made it possible to develop a snow-density map of the U.S.S.R. The map was divided snow-density map of the U.S.S.R. The map was divided into five general categories of SCD, ranging from values less than or equal to 0.21 g/cu cm at interior stations with very light winds to values greater than or equal to 0.31 g/cu cm at arctic locations with strong winds. Since this literature survey indicated that the reported Soviet SCD values were incorrect due to instrustrong winds. Since this literature survey indicated that the reported Soviet SCD values were incorrect due to instrumental errors, adjustments to the data in this study were required. Month-to-month investigation of the SCD data revealed a gradual increase in density from November to March and that the SCD values under forest canopies averaged from 4 to 14% lower than those recorded in open areas. Also included in this report are 1) a compilation of pertinent passages in the Soviet literature on SCD, 2) a map showing the location of SCD measurements, and 3) an average winter wind speed chart for the U.S.S.R.

CR 84-23 EFFECT OF SNOW ON VEHICLE-GENERATED SEISMIC SIGNATURES

Albert, D.G., Aug. 1984, 24P., ADB-090 976, 10 refs. 40-35ÁA

MILITARY OPERATION, SNOW COVER EF-FECT, SEISMOLOGY, DETECTION, VEHICLES, ATTENTUATION, ACOUSTICS, SEASONAL VARIATIONS.

VARIATIONS.

Vehicle-generated seismograms recorded under summer and winter conditions at Fort Devens, Massachusetts, are analyzed and compared. The data were recorded using three-component geophones located just beneath the ground surface and microphones mounted on tripods 0.3 m tall. Winter data were recorded when a 0.7-m-thick snow cover was present. The filtering effect of this snow cover on the seismic data was striking. The appearance and frequency content of the recorded ground modion changed dramatically from summer to winter because snow attenuates the acoustic-to-seismic coupled energy. These changes were verified by magnitude-squared coherence analysis and by a simple Wiener prediction

model. Automatic vehicle classification algorithms will have to account for these effects if the algorithms are to operate successfully in the presence of snow.

CRYSTALLINE STRUCTURE OF UREA ICE SHEETS USED IN MODELING EXPERIMENTS IN THE CRREL TEST BASIN.

Gow. A.J., Sep. 1984, 48p., ADA-148 434, 29 refs.

ICE CRYSTAL STRUCTURE, UREA, SEA ICE, ICE MECHANICS, GRAIN SIZE, ICE MODELS, ICE SHEETS, TESTS.

ICE SHEETS, TESTS.

This report describes the growth characteristics and crystalline textures of urea ice sheets which are now used extensively in the CRREL test besin for modeling sea ice. The sims of the report are to describe the different kinds of crystalline texture encountered in urea ice sheets and to show that even small variations in texture can drastically influence the mechanical behavior of urea ice sheets. Standard petrographic techniques for studying microstructure in thin sections were used on 24 urea ice sheets. These investigations entailed observations of the crystalline texture of the ice (including details of the subgrain structure), grain size measurements, and studies of the nature and extent of urea entrapment and drainage patterns in the ice. Increased knowledge of the factors controlling the crystalline characteristics of urea ice sheets has progressed to the point where test basin researchers at CRREL are now able to fibricate ice sheets with prescribed structures leading to predictable mechanical properties. predictable mechanical properties.

CR 84-25 REVIEW OF ANTITANK OBSTACLES FOR WINTER USE.

FAIRBANKS.
Radar and wide-angle reflection and refraction (WARR) profiles were obtained across three buried sections of the trans-hisaks pipeline near Fairbanks in late April 1983. A broad-bank, pulsed radar operating in the VHF (very high frequency) range was used. The surficial geology at the three sites consisted of gravel (dredge tallings), silt and alluvium, respectively, and the sites were marginally frozen or completely thawed. May the sites were marginally frozen or completely thawed. At the gravel site the pipe (approximately 2 m deep) and an underlying water table were easily visible. There was no radar signature of the pipe at the silt site: the WARR profiles verified the high absorption of the material. The response was marginal at the alluvium conditions about the pipe makes radar a generally poor choice for mapping freeze-thaw boundaries but a good choice for estimating material state and moisture content. estimating material state and moisture of

POLYETHYLENE GLYCOL AS AN ICE CON-TROL COATING.

Itagaki, K., Dec. 1984, 11p., ADA-150 466, 13 refs. 40-3577

PROTECTIVE COATINGS, ICE CONTROL, ICE PREVENTION, RESINS, MELTING POINTS, SNOW ACCUMULATION, ICE ACCRETION, COUNTERMEASURES, TESTS.

The properties of polyethylene glycol (PBG) as a sacrificial ice control coating are discussed. PBG is effective longer than many single component coatings, and it has low toxicity and a high flash point. The results of preliminary experiments on PBG's ability to control snow accumulation on a panel and ice accumulation on a cryogenic tank are also

REVERSE PHASE HPLC METHOD FOR ANALYSIS OF TNT, RDX, HMX AND 2,4-DNT IN MU-

NITIONS WASTEWATER.

Jenkins, T.F., et al, Dec. 1984, 95p., ADA-155 983, Refa. p.36-38.

Bauer, C.F., Leggett, D.C., Grant, C.L. 40-3578

WATER POLLUTION, WASTE DISPOSAL, EXPLOSIVES, CHEMICAL ANALYSIS, DETECTION, TESTS, MILITARY FACILITIES, STATISTICAL ANALYSIS.

TICAL ANALISIS.

An analytical method was developed to determine the concentrations of HMX, RDX, TNT and 2,4-DNT in munitions wastewater. The method involves dilution of an aqueous sample with an equal volume of methanol-acconditive solvent mixture, filtration through a 0.4 micron polycarbonate membrane and analysis of a 100 microl. subsample by Reversephase, high-performance liquid chromatography using an LC-8 column. Retention times of these four analyses, their secondary and imputitive expected in wastewater. 8 column. Retention times of these four analytes, their degradation products, and impurities expected in wastewater matrices were determined for two eluent compositions. An eluent of 50% water, 38% methanol and 12% acctonitrile successfully separated HMX, RDX and TNT from each other and the potential interferents. The method provided linear calibration curves over a wide range of concentrations.

IMPACT OF SLOW-RATE LAND TREATMENT ON GROUNDWATER QUALITY: TOXIC OR-

Parker, L.V., et al, Dec. 1984, 36p., ADA-153 253, Refs. p.19-21.

Jenkins, T.F., Poley, B.T.

40-3361 GROUND WATER, WASTE TREATMENT, WATER TREATMENT, LAND RECLAMATION, SEEPAGE, ORGANIC NUCLEI, ENVIRONMEN-TAL IMPACT

TAL IMPACT.

The removal efficiency for 16 organic substances in wastewater was studied on an outdoor, prototype slow-infiltration system. The initial concentration of each of these substances in the wastewater was approximately 50 microgram/L. Removal was via volatilization during spray application and subsequent adsorption in the soil. The percent removal during spraying could be estimated from the liquid-phase transfer coefficient; losses were up to 70% for the most volatile components. The total percent removal for the system, based on the concentration in the percolate, was more than 98% for all substances. Only chloroform, which has a low octanol-water coefficient and according to the literature is not degradable aerobically, was continuously detected in the percolate. The major final removal mechanisms are believed to be volatilization and biodegradation-biotransformation. Breakthrough of several other organics in early spring as a result of application during the colder months was also observed. The two substances that were PCBs were apparently slowly lost from the system, probably by volatilization. The behavior of diethylphthalate was different in the two soils tested but was more recalcitrant than expected. than expected

CR 84-31 DETECTION OF BURIED UTILITIES. VIEW OF AVAILABLE METHODS AND A COM-PARATIVE FIELD STUDY

Bigl, S.R., et al, Dec. 1984, 36p., ADB-090 068L, 21 refs.

Henry, K.S., Arcone, S.A

UNDERGROUND FACILITIES, UTILITIES, DE-TECTION, FROST PENETRATION, MAGNETIC SURVEYS, GEOPHYSICAL SURVEYS, EARTH-

WORK.

Locating buried utilities is often necessary for repair, servicing, or prevention of damage when earthwork is to be conducted in a particular area. Of the many methods available for detection of buried utilities, those in most wide-spread use are magnetic induction, magnetometry, and radiofrequency tracking. Comparative field tests of 11 locators using these three operating methods were conducted in Hanover, New Hampahire, and eight of these were further tested at the U.S. Military Academy, West Point, New York, and the Stewart Army Subpost, Newburgh, New York, and the Stewart Army Subpost, Newburgh, New York and the West Point and Newburgh, the nine sites included a variety of utility types including iron and steel pipe, cable, vitreous

tile and plastic, as well as different terrain and groundcover characteristics. Tests with the radiofrequency tracking locators were insufficient to evaluate their ability to locate nonmetallic pipe or to judge if one locator was superior to the other. Although not statistically different, slightly more accurate average readings were obtained with the magnetic induction and magnetometer instruments over cable than over pipe. Shallow utilities (<3.5 ft) were located slightly more accurately than deeper ones. In general, the low-to mid-priced magnetic induction locators appeared to be the most cost effective. Problems with accuracy in utility location occurred mainly at sites with steep topography owhere utilities were in very close proximity. Successful operation of the instruments required only a small amount of training.

SHORELINE EROSION PROCESSES: ORWELL

LAKE, MINNESOTA. Reid, J.R., Dec. 1984, 101p., ADA-152 952, Refs. p.34-56.

SHORE EROSION, SLOPE PROCESSES, LAKE WATER, BANKS (WATERWAYS), GROUND THAWING, SEDIMENT TRANSPORT, WATER WAVES, RESERVOIRS, SHORELINE MODIFICATION, RAIN, SEASONAL VARIATIONS, METEOROLOGICAL FACTORS.

METEOROLOGICAL FACTORS.

Orwell Lake, in west-central Minnesota, is a flood-control, water-management reservoir first impounded in 1953. Subsequent erosion of the shoreline and a lack of knowledge of slope erosion processes in this region prompted this study to identify and quantify the processes there. The processes were measured at selected sites between June 1980 and June 1983. Brosion of the banks is primarily caused by three processes: rain, frost thaw, and waves. The first two processes tend to move sediment to the base of the steep alopes, forming a relatively gentle surface of accumulation. Wave action then tends to move this sediment into the lake. Analysis of the data collected over three years has confirmed that wave action is the dominant erosion process, providing almost 77% of the erosion during the years has confirmed that wave action is the dominant crosson process, providing almost 77% of the crosson during the 1981-82 study year. During the 1981 high pool level, 2,089 Mg of sediment, mostly colluvium, was removed from the lower slopes by wave action striking the 1.62 km of croding shoreline. More than 4,300 Mg was croded by waves accompanying the higher pool levels of 1982.

ICE FORCES ON RIGID, VERTICAL, CYLIN-DRICAL STRUCTURES. Sodhi, D.S., et al, Dec. 1984, 36p., ADA-151 393, 32

VELOCITY, EXPERIMENTATION.

A small-scale experimental study was conducted to characterize the magnitude and nature of ice forces during continuous crushing of ice against a rigid, vertical, cylindrical structure. The diameter of the structure was varied from 50 to 500 mm, the relative velocity from 10 to 210 mm/s, and the tee thickness from 50 to 80 mm. The ice tended to fail repetitively, with the frequency of failure termed the characteristic frequency. The characteristic frequency varied linerally with velocity and to a small extent with structure diameter. The size of the damage zone was 10 to 50% of the ice thickness, with an average value of 30%. The maximum and mean normalized ice forces were strongly dependent on the aspect ratio (structure diameter/ice thickness) are the structure diameter to the sepect ratio (structure diameter/ice thickness). dependent on the aspect ratio (structure diameter/ice thickness). The forces increased significantly with decreasing aspect ratio, but were constant for large aspect ratio. The maximum normalized forces appeared to be independent of strain role.

PROTOTYPE DRILL FOR CORE SAMPLING FINE-GRAINED PERENNIALLY FROZEN GROUND.

DRILLS, AUGERS, PERMAFROST THERMAL
PROPERTIES, FROZEN GROUND TEMPERATURE, CORING, SAMPLING, GROUND ICE,
GRAIN SIZE, TEMPERATURE EFFECTS, COST ANALYSIS.

ANALYSIS.

An inexpensive drill has been modified to provide researchers with the ability to suger an open hole or to acquire continuous, undisturbed 76-mm-diam core samples of a variety of perennially frozen materials that are suitable for chemical and petrographic analysis. It was developed by field testing in support of research from 1980 to 1983. Operation of the drill is based mainly on using a minimum of power to cut through frozen ground with tungsten carbide cutters on a CRREL coring suger. The ice content, temperature and grain size of the frozen sediments are important variables determining the sampling depth. Perennially frozen sediments with temperatures in the range of -0.5 C to -8.5

C have been continuously cored with this drill. Drilling and sampling are most efficiently conducted when ambient air temperatures are below freezing and the active layer is frozen. The self-contained lightweight drill is readily transportable off-road by helicopter or tracked vehicle, or by towing over roads. It is locally self-mobile by use of a winch. Total cost of the drill and modifications is estimated at approximately \$10,000.

CR 85-02 EFFECT OF NONUNIFORM SIZE ON INTER-NAL STRESSES IN A RAPID, SIMPLE SHEAR FLOW OF GRANULAR MATERIALS. PART 1. TWO GRAIN SIZES.

Shen, H.H., Feb. 1985, 18p., ADA-154 045, 18 refs.

SHEAR FLOW, PARTICLE SIZE PISTRIBUTION, MICROSTRUCTURE, MATERIALS, STRESSES, STRAINS, AVALANCHE MECHANICS, MATHEMATICAL MODELS.

Existing theories that predict the stress-strain rate relationship in a rapidly sheared granular flow can only treat materials that are made of single-size particles. However, granular flows usually involve materials of mixed sizes. It has been observed in many laboratory studies that size distribution has a significant effect on the flow of a granular material. Despite its importance, no quantitative theory has been devised that can explain the effect of size distribution. An analytical model is developed here to quantify the stresses in a mixture of spheres with two different sizes and identical material properties. Binary collisions between adjacent particles are considered as the dominating stress-generating mechanism. Comparisons between the theoretical results and the existing laboratory data show good agreement. Existing theories that predict the stress-strain rate relationship

EFFECT OF NONUNIFORM SIZE ON INTER-NAL STRESSES IN A RAPID, SIMPLE SHEAR FLOW OF GRANULAR MATERIALS. PART 2.

MULTIPLE GRAIN SIZES.
Shen, H.H., Feb. 1985, 20p., ADA-154 046, 19 refs.

SHEAR FLOW, PARTICLE SIZE DISTRIBUTION, MICROSTRUCTURE, STRESSES, MATERIALS,

SHEAR STRESS.

In the past all theoretical analyses for rapdily sheared granular flows assumed that the granular solids are either disks or spheres and are uniform in size.

However, natural materials that create these granular flows are in general irregular in shape and have various spectra of sizes. The stress and rate of energy dissipation levels in granular flows are significantly influenced by the size distribution. In part 1 of this report series (see 40-38, CR 85-2) the formulation of the contribution street in the stress of the street report series (see 40-38, CR 85-2) the formulation of the constitutive equations considering a two-size granular mixture is presented, where the ratio of the two sizes is nearly one. Here, in part 2, the constitutive equations for a two-size mixture are extended to include a general size ratio. In addition, a complete spectrum of size distribution is incorporated, which allows the quantification of the size distribution effect in the most general way. In analyzing the stresses, intergranular collision is assumed to be the major dynamic activity at the microscopic level. Because of the present limited knowledge of treating shape effects, the analysis is confined to the flow of either disks or spheres. The result of this work provides necessary information for a more realistic analysis of natural and industrial granular flows.

CR 85-04 PROPULSION TESTS IN LEVEL ICE ON A MODEL OF A 140-FT WTGB ICEBREAKER. Tatinclaux, J.C., Mar. 1985, 13p., ADA-154 075, 6

KINETIC FRICTION COEFFICIENT OF ICE Forland, K.A., et al, Mar. 1985, 40p., ADA-155 035, 23 refs.

Tatinclaux, J.C. 39-3957

JS-3977 ICE SOLID INTERFACE, ICE FRICTION, ICE HARDNESS, SURFACE ROUGHNESS, ENGI-NEERING, VELOCITY, TESTS.

This study investigates the relative influence of various parameters on the kinetic friction coefficient between ice and different ters on the kinetic friction coefficient between ice and different surfaces. Friction tests were performed with urea-doped, columnar ice, studying the parameters of normal pressure, velocity, type of material roughness, ice orientation, ice hardness and test configuration. Tests were conducted by pulling a sample of ice over a sheet of material and by pulling a sample of material over an ice sheet. An ambient temperature of -1.5 was maintained throughout, and the ice surface hardness was measured using a specially designed. apparatus. The results of the friction tests revealed that the behavior of kinetic friction coefficient with varying velocity was significantly influenced by the test configuration and material roughness. The magnitude of the kinetic friction coefficient was also affected by varying normal pressure, surface roughness and ice hardness. Additional guidelines for standardized ice friction tests and future investigations The results of the friction tests revealed that

MEASURING THERMAL PERFORMANCE OF BUILDING ENVELOPES: NINE CASE STUD-

Flanders, S.N., Mar. 1985, 36p., ADA-155 083, 13 refs.

THERMAL INSULATION, BUILDINGS, HEAT FLUX, THERMAL MEASUREMENTS, THERMOCOUPLES, COMPUTER APPLICATIONS, COST ANALYSIS, WIND FACTORS.

Nine buildings at Ft. Devens were the object of a study employing heat flux sensors, thermocouples, a computer-controlled data acquisition system and infrared thermography. The purpose was to measure the R-values of those buildings to determine their economic potential for improved insulation. The sample included four frame buildings, two masonry buildings, and three frame buildings with brick facing. The technique for measuring R-values proved repeatable and accurate within 15%. Sampling a small representative sample sufficiently characterizes the entire stock of buildings. Measurement is more important for poorty insulated buildings, since the beginning R-value has a drastic impact on the budget for a cost-effective reinsulation project. At Ft. Devens, installing an external Styrofoam insulation system on concrete block barracks has a savings-to-investment ratio of about 1.4

SNOW THERMAL PROPERTIES, SNOW HEAT FLUX, HEAT TRANSFER, WATER VAPOR, TEMPERATURE GRADIENTS, POROUS MATERIALS, THERMAL CONDUCTIVITY, CONVECTION, MATHEMATICAL MODELS, IATENT HEAT EXPERIMENTATION LATENT HEAT, EX METAMORPHISM (SNOW). EXPERIMENTATION,

METAMORPHISM (SNOW).

Large temperature gradients applied to a snow cover drive water vapor upwards and result in rapid recrystallization of snow crystals. The same temperature gradients create gradients of sir density that can cause flows of sir through the snow cover. The formalism necessary to describe these flows is developed here in an effort to include the convenction of vapor in the understanding of snow metamorphism. The theory of convection through porous media

is extended to include the transport of water vapor, which is important because of its latent heat. Results are presented in terms of a Lewis number, defined as the ratio of thermal in terms of a Lewis number, defined as the ratio of thermal to mass diffusivities. For Lewis numbers greater than 1.0, phase change intensifies convection, and for Lewis numbers less than 1.0, phase change returds convection. Two boundary conditions of special interest in the study of snow, a constant heat flux bottom and a permeable top, are investigated.

CR 85-10 REVIEW OF METHODS FOR GENERATING SYNTHETIC SEISMOGRAMS.

ANALYSIS OF RIVER WAVE TYPES. Ferrick, M.G., June 1985, 17p., ADA-158 683, For another source see 39-3098. 20 refs.

40-1050 WATER WAVES, RIVER FLOW, RIVER ICE, DAMS, UNSTEADY FLOW, ICE JAMS, RUNOFF. FRICTION, MATHEMATICAL MODELS.

PRICTION, MATHEMATICAL MODBLS.
In this paper, we consider long-period, shallow-water river waves that are a consequence of unsteady flow. River waves result from hydroelectric power generation or flow control at a dam, the breach of a dam, the formation or release of an ice jam, and rainfall/rumoff processes. The Saint-Venant equations are generally used to describe river waves. Dynamic, gravity, diffusion, and kinematic river waves have been defined, each corresponding to different forms of the momentum equation and each applying to some subset of the overall range of river hydraulic properties and time scales of wave motion. However, the parameter ranges corresponding to each wave description are not well ranges corresponding to each wave description are not well defined, and the transitions between wave types have not been explored. This paper is an investigation into these areas, which are fundamental to river wave modeling. The analyzis is based on the concept that river wave modeling. The analyzis is based on the concept that river wave behavior is determined by the balance between friction and inertia.

CR 85-13 ELECTROMAGNETIC MEASUREMENTS OF MULTI-YEAR SEA ICE USING IMPULSE RA-DAR.

Kovacs, A., et al, Sep. 1985, 26p., ADA-160 737, 11 refs.

Morey, R.M. 40-1544

SEA ICE, ELECTROMAGNETIC PROPERTIES, ICE BOTTOM SURFACE, MARINE GEOLOGY, GEOPHYSICAL SURVEYS, ELECTRICAL RESISTIVITY, BRINES, DIELECTRIC PROPERTIES.

Sounding of multi-year sea ice, using impulse radar operating in the 80- to 500-MHz frequency band, has revealed that the bottom of this ice cannot always be detected. This paper discusses a field program aimed at finding out why this is so, and at determining the electromagnetic (BM) properties of multi-year sea ice. It was found that the

bottom of the ice could not be detected when the ice structure had a high brine content. Because of brine's high conductivity, brine volume dominates the loss mechanism in first-year sea ice, and the same was found true for multi-year ice. A two-phase dielectric mixing formula, used by the authors to describe the EM properties of first-year sea ice, was modified to include the effects of the gas pockets found in the multi-wear sea ice. in the multi-year sea ice.

VEGETATION AND ENVIRONMENTAL GRADIENTS OF THE PRUDHOE BAY REGION.

ALASKA. Walker, D.A., Sep. 1985, 239p., ADA-162 022, Refs. p.122-135. 40-1790

TUNDRA, VEGETATION, TEMPERATURE GRADIENTS, PLANTS (BOTANY), COASTAL TOPOGRAPHIC FEATURES, ICE WEDGES, SNOW DEPTH, TEMPERATURE EFFECTS, LOESS, HUMMOCKS, SOIL WATER, UNITED STATES—ALASKA.

The Prudhoe Bay region is a particularly interesting area of tundra because of its well-defined and steep environmental The Prudhoe Bay region is a particularly interesting area of tundra because of its well-defined and steep environmental gradients, the combination of which has not been described elsewhere in the Arctic. It is a region of wet coastal tundra that has a unique substrate pH gradient, due in part to its coastal location. The prevailing northeast winds distribute locas from the Sagavanirktok River over most of the region. Areas downwind from the river have alkaline undra with a gradient of declining soil pH values away from the river: the northwest portion of the region is not downwind from the river and consequently has acidic tundra. The coastal temperature gradient is among the steepest in the Arctic. Three of Young's (1971) four floristic zones, which are based on the amount of total summer warmth, are present within the region. The effects of the temperature of plants in the flora and the increase of the total number of plants in the flora and the increase of the total number of plants in the flora and the increase of the total number of plants in the flora and the increase of the total number of plants in the flora and the increase of the total number of plants in the flora seem moves inland. The predominantly wet landscape also creates steep vegetation gradients within elevation changes of a few centimeters. Small hummer mocks and higher microsites associated with ice wedge polygon relief may be elevated only 10-25 cm above the level of asturated soils but can support rich mesic tundra plant communities.

TNT, RDX AND HMX EXPLOSIVES IN SOILS AND SEDIMENTS. ANALYSIS TECHNIQUES AND DRYING LOSSES.

EXPLOSIVES, FREEZE DRYING, SOIL POLLU-TION, SEDIMENTS, CHEMICAL ANALYSIS, COUNTERMEASURES, DRYING, ADSORPTION, ABSORPTION, TESTS.

TION, ABSORPTION, TESTS.

A method for the analysis of TNT, RDX and HMX explosives in soils and sediments has been devloped. It consists of methanol extraction followed by reversed-phase high performance liquid chromatography using 10% acetonistile/40% methanol/50% water as the eluant. This method was used to study the effect of various drying techniques upon the recovery of TNT, RDX and HMX from soil and sediment samples contaminated with high (%) and low (microgram/g) levels of these explosives. For highly contaminated samples, complete recovery of TNT and RDX was obtained using freeze drying while air drying at room temperature resulted in greater than 90% recovery for both explosives. Other techniques, such as oven drying at 105C, oven drying at 45C, microwave oven drying, and drying under inflared lamps, all resulted in greater losses, with TNT and RDX recoveries ranging from 76 to 90%. Drying losses were not due to simple volatilization but rather to chemical reaction and/or sorption. For soil and sediment samples containing low levels of TNT, RDX and HMX, recoveries of all three explosives were quantitative for all of the above drying techniques.

MECHANICAL PROPERTIES OF MULTI-YEAR SEA ICE. PHASE 2: TEST RESULTS. Cox, G.F.N., et al, Oct. 1985, 81p., ADA-166 333, 10

EXPLOSIVES, DRILLING FLUIDS, MILITARY OPERATION, POLLUTION, MUD, CHEMICAL COMPOSITION, ENVIRONMENTAL PROTECTION, ADSORPTION, ABSORPTION, ANALYSIS (MATHEMATICS).

TION, ADSORPTION, ABSORPTION, ANALYSIS (MATHEMATICS).

Concern over the environmental fate of explosives has brought about development of sensitive analytical methods for measuring them in groundwater. In turn this concern has been extended to validating the sampling procedures for groundwater. This report addresses the potential effects of residual drilling muds on the analysis for explosive contaminants (TNT, DNT, RDX and HMX) in monitoring wells. The approach was to determine sorption isotherms for each contaminant. Sorption appeared to be independent of solids concentration. Linear isotherms were obtained for RDX and HMX over a range of analytic concentration; therefore, a single constant can be used to estimate the amount sorbed when the solution concentration is known. Isotherms for TNT and DNT were not linear, however. Scatchard analysis suggested that the isotherms for these analytes could be resolved into two predominant components a linear component above a certain sorbed quantity and a Langmuir-type component below this quantity. The experimental data were fitted by regression analysis using the appropriate model. The equations developed can be used to predict the sorbed fraction (analytical bias) for any combination of solids and analyte concentration. The amounts of bentonite found in some existing wells do not appear to be sufficient to cause significant bias in analyses for these explosive contaminants.

CONSTITUTIVE RELATIONS FOR A PLANAR, SIMPLE SHEAR FLOW OF ROUGH DISES. Shen, H.H., et al, Dec. 1985, 17p., ADA-163 147, 10 refs.

Hopkins, M.A. 40-3367

SHEAR FLOW, SURFACE ROUGHNESS, FLOW RATE, FRICTION, STRESSES, AVALANCHES, COMPUTER APPLICATIONS, TESTS.

COMPUTER APPLICATIONS, TESTS.

Stresses developed in a rapid, simple shear flow of disks are quantified. Collisional momentum transfer is considered to be the dominant stress generating mechanism. The disks are inelastic and frictional. The restitution coefficient of friction together determine the transfer of momentum and dissipation of energy during a collision. The frictional coefficient generates and maintains a rotational motion of disks. The total fluctuation motion of disks consists of two translational modes and one rotational mode. The rotational mode is found to depend on both the restitution and friction coefficient. Equipartitions of energy among all modes of motion is sheent. The mean rotation, however, depends only on the mean flow gradient. The analysis assumes a constant magnitude for all fluctuation modes. Comparison with a computer simulated disk flow shows good agreement. This implies that the distribution of stresses.

CR 85-21 ICE-CORING AUGERS FOR SHALLOW DEPTH SAMPLING.

FLOW.

Reperiments to study the melting of a horizontal ice sheet with a flow of water above it were conducted in a 35-m-long refrigerated flume, with a cross section of 1.2x1.2 m. Water depth, temperature, and velocity were varied as well as the temperature and initial surface profile of the ice sheet. The heat transfer regimes were found to consist of forced turbulent flow at high Reynolds numbers with a transition to free convection heat transfer. There was no convincing evidence of a forced laminar regime. The data were correlated for each of the regimes, with the Reynolds number, Re, or the Grashof number combined with the Reynolds number.

SPECIAL REPORTS

SR 76-01 CLIMATIC AND SOIL TEMPERATURE OBSER-VATIONS AT ATKASOOK ON THE MEADE RIVER, ALASKA, SUMMER 1975. Haugen, R.K., et al, May 1976, 25p., ADA-025 193,

Brown. J., May, T.A.

22-1197 CLIMATOLOGY, AIR TEMPERATURE, SOIL TEMPERATURE, UNITED STATES—ALASKA—

ATKASOOK.

Au temperatures measured during the summer of 1975 indicated that the Meade River site, 120 km aouth of Barrow, has a distinctly continental summer temperature pattern in comparison to Barrow, which is cooler and has a smaller delly temperature fluctuation. Stepwise multiple regression analysis indicated a significant relationship between current and previous day's air temperature and all of the (near) surface temperatures examined. Precipitation and pan evaporation were not significantly related 'n terrain surface temperatures. At the wet site, the warmest subsurface temperatures were measured in a shallow pond. Dry site temperatures were warmer and showed less variation with depth in comparison to wet site temperatures.

REGIONALIZED FEASIBILITY STUDY OF COLD WEATHER EARTHWORK.

Roberts, W.S., July 1976, 190p., ADA-029 936, M.S. thesis. 91 refs. 32-1238

COLD WEATHER OPERATION, EARTHWORK, SOIL STRUCTURE, MAPPING, ECONOMIC ANALYSIS.

ANALYSIS.
A regional approach is used to delineate areas in Canada and the United States, in which selected earthwork operations should receive careful consideration for winter execution. Soil texture and soil "form" or physical site environment are deemed important physical factors in the economic feasibility of cold weather earthwork. Summary maps showing significant soil forms and related feasible earthwork operations are presented. A general discussion of the importance of the soil form in the economic feasibility of winter earthwork is included. A summary is presented which shows, with respect to physiographic sections, the salient information and conclusions developed by this study. At least 94% of physiographic sections have two or more winter earthwork operations that are deemed feasible. Only 5 of 213 sections considered do not have any earthwork operations that appear feasible in the winter season.

THERMOINSULATING MEDIA WITHIN EM-BANKMENTS ON PERENNIALLY FROZEN SOIL

Berg, R.L. May 1976, 161p., ADA-062 447, Ph.D. 120 refs. 32-1239

32-1239
EMBANKMENTS, THERMAL INSULATION,
PERMAPROST PRESERVATION, PROTECTIVE COATINGS, SOIL S EMATICAL MODELS. STABILIZATION, MATH-

EMATICAL MODELS.

Most transportation facilities proposed for arctic and subarctic regions will be constructed on embankments. Incorporation of a thermoinsulating layer within the embankment may permit use of reduced quantities of embankment material. Thermal design and analysis procedures applicable to embankments are reviewed and a two-dimensional numerical method coupling heat and mast transfer and vertical displacement is proposed. The modified Berggrer equation, a method developed by Lachenbruch, and a finite difference technique are used to illustrate design and analysis methods for insulated embankments on permafrost. Most applications of insulation have been in seasonal frost areas but a few test sections have been constructed on permafrost. Stability of thermal and physical properties is a desirable characteristic of thermoinsulating layers. Moisture absorption causes increased thermal conductivity and degradation of strength of some insulating materials. Several types of moisture barriers have been used but the most successful have been polyethylene sheets. SR 76-04

CREEP THEORY FOR A FLOATING ICE

Nevel, D.E., June 1976, 98p., ADA-026 122, 73 refs. 32-1240

FLOATING ICE, ICE CREEP, LOADS (FORCES), STRESSES, ICE MECHANICS, MATHEMATI-CAL MODELS.

The problem investigated is the prediction of the deflection and stresses in a floating ice sheet under loads which act over a long period of time. A review of analytical methods for predicting the bearing capacity of an ice sheet is given. The problem is formulated by assuming the ice is isotropic with a constant Poisson's ratio. The shear modulus is

assumed to obey a linear viscoelastic model. The specific model selected is a series of one Maxwell model and two Voigt models. One of the Voigt models has a negative spring constant which produces tertiary creep. The ice model schibits a primary, secondary, and tertiary creep response, similar to that observed in uniaxial creep tests of ice. The material properties in the viscoelastic model may be a function of the vertical position in the ice sheet, but all these material properties must be proportional to the same function of position. Using the thin-piate theory for the floating ice sheet, the solution is obtained for the deflection and stresses in the ice sheet for primary, secondary, and tertiary creep regions. It is then shown that for a load that is not distributed over a large area, the time-dependent of the load's distribution. For the elastic case, the stress significantly depends upon the load's distribution. Results are given for the deflection and stresses as a function of time and distance from the load. The maximum deflection and stresses occur at the center for the load. At this point the deflection increases with time, while the stresses decrease.

SP 76-05

UTILITY DISTRIBUTION SYSTEMS IN ICE-

Aamot, H.W.C., May 1976, 63p., ADA-026 956.

UTILITIES, WASTE DISPOSAL, SEWAGE DISPOSAL, SUBARCTIC LANDSCAPES, ICELAND. POSAL, SUBARCTIC LANDSCAPES, ICELAND. The study reports on new developments and special problems or solutions in water distribution systems, sewage collection systems, heat distribution and electric transmission system. Cold weather considerations are highlighted. For water and sewage transport, the use of ductile iron, concrete and plastic materials is reported. Utility lines are generally placed individually, utilidors are too expensive for most installations except in some city center locations. Heat distribution with hot water from goothermal wells is mostly one-way piping. After heating, the water is discharged through the sewage system. Street heating is being expanded. With electric distribution, the use of self-supporting aerial cables is becoming popular because it is very cost-effective and reinable. Within the city, all distribution is under ground. Arcing of isolators on high voltage transmission lines due to salt from the ocean atmosphere is being reduced with silicone fluids.

INFLUENCE OF INSULATION UPON FROST PENETRATION BENEATH PAVEMENTS. Eaton, R.A., et al, May 1976, 41p., ADA-026 957, 10

Dukeshire, D.E.

32-1242

PAVEMENTS, SUBGRADE PREPARATION, FROST HEAVE, FROST PENETRATION, CEL-LULAR MATERIALS, THERMAL INSULATION. LULAR MATERIALS, THERMAL INSULATION. In order to minimize differential frost heaving caused by variable in-situ soil conditions, granular material is placed on top of the frost-susceptible subgrade. This creates a uniform layer to bridge subsurface irregularities in soil properties. This method of protecting the pavement structure can be costly. A method of reducing the amount of granular material is the use of a thermal insulating layer beneath all or part of the base course which prevents freezing temperatures from reaching the non-uniform subgrade. A test road which includes styrofoam board insulated test sections was constructed at CRREL in 1973. A transition section was built between a control section and an insulated section minimize the drastic difference in frost penetration and resultant differential frost heave. Large temperature differences were measured between the insulated 1.3 do onventional sections, frost penetrations were one-third as deep beneath ences were measured between the insulated that conventional sections, frost penetrations were one-third as deep beneath the insulated section, differences in frost heave were negligible, and pavement deflections were approximately the same on the two sections. Surface differential icing did occur between the control and insulated sections.

SKYLAB IMAGERY: APPLICATION TO RESER-VOIR MANAGEMENT IN NEW ENGLAND McKim, H.L., et al, Sep. 1976, 51p., ADA-030 329, 24

Gatto, L.W., Merry, C.J., Haugen, R.K.

32-1243 AERIAL SURVEYS, SPACEBORNE PHOTOGRA-PHY, MAPPING, RESERVOIRS.

THI, MAPPING, RESERVOIRS.

The purpose of this investigation was to determine the utility of Skylab S190A and B photography for providing reservoir management information in New Ragland. LANDSAT, Skylab S190A and S190B and RB-57/RCS images were reduced to a common scale of 1:63,360 for a mapping base to demonstrate the extent to which the imagery could be utilized in the preparation of reconnaissance land use maps. Visual interpretations were accomplished on original NASA

color infrared S190A/B and RB-57/RC8 transparencies and a LANDSAT false color print made in-house. Ancillary data were not used during the mapping exercise to eliminate bias in the comparisons and to ensure that the results were derived strictly from interpretations of tones and textures on the photography. The classification scheme was a modified version of the U.S. Geological Survey Land Use Classification System for use with remote sensor data. The relative utility of the multiband imagery in identifying and quantifying hydrologic factors was evaluated. The land use statistics for two small watershods were determined and the effects of these land use factors were appraised for possible contribution to runoff potential. This appraisal indicated that basin topography and the nature of runoff may be more important factors in predicting volume of runoff from a watershed than land use factors. Companisous of the usefulness of the various imagery systems are made.

SK 75-56 SURVEY OF ROAD CONSTRUCTION AND MAINTENANCE PROBLEMS IN CENTRAL

AT.ARKA. Clark, B.F., et al, Oct. 1976, 36p., ADA-032 085, 21 refs.

Simoni, O.W.

32-1244
ROADS, WINTER MAINTENANCE, ROAD ICING, PERMAPROST PRESERVATION, THERMAL INSULATION, EROSION.

MAL INSULATION, EROSION.

A survey of road construction and maintenance problems in central Alaska is presented. The problems of poor fill and foundation material, permatrost degradation under pavement and shoulders, alope instability, water erosion, road icing from subsurface seepage and culvert icing are described. Possible solutions to road maintenance problems in central Alaska include the use of insulating materials in permatrost areas, MESL construction when non-frost-susceptible soils are unavailable, and the use of improved drainage in areas where extensive icing occurs. Bridge damage, erosion of sidehill cuts and embankment instability are also discussed and potential solutions are given.

SR 76-09 COMPRESSED AIR SEEDING OF SUPER-COOLED FOG.

Hicks, J.R., Oct. 1976, 9p., ADA-040 819, 1 ref. 32-1245

SUPERCOOLED FOG, CLOUD SEEDING, FOG DISPERSAL, ICE CRYSTAL FORMATION.

DISPERSAL, ICB CRYSTAL FORMATION.
Two series of experiments, 25 in a light fog and 25 in a heavy fog, were conducted in the CRREL cold cloud chamber. Compressed air was used to glaciate the 4C fog. The gage air pressure was 413.7 kPa. These tests showed that the number of ice crystals produced exceeded the number of water droplets in the fog by a factor of 21 for a light fog and 133 for a heavy fog. Approximately 2.6 times as many ice crystals were created in a heavy fog than were created in a light fog.

SR 76-10 TEMPORARY ENVIRONMENT. COLD RE-

GIONS HABITABILITY. Bechtel, R.B., et al, Oct. 1976, 162p., ADA-032 353, Bibliography p. 115-116. Ledbetter, C.B.

32-1246

IRONMENTS, HUMAN FACTORS ENGI-NEERING, BUILDINGS.

NEBRING, BUILDINGS.

After classifying government environments in Alaaka and studying four Federal Aviation Administration (FAA) and three Aircraft Control and Warning (Ac&W) stations (in Phases 1 and 2), a cold regions environmental psychology behavior setting survey was made of Fort Wainwright, Alaaka, to complete Phase 3. Phase 4 analyzed Fort Wainwright, Alaaka, to complete Phase 3. Phase 4 analyzed Fort Wainwright data and compared it with the FAA and Ac&W data and previous studies. The military locations could be characterized as temporary environments. The military environment in fiftered from civilian environments in the behavioral areas of religion, government and professionalism. FAA stations were found to have the richest environment and Ac&W stations the most deprived. Yet Ac&W stations compensated by providing greater leadership opportunities. Small installations had an advantage over large installations in the participation level of their populations in recreational and other activities. Pamily housing, transient housing, barracks and work environments of Fort Wainwright were studied. Habitability guidelines were suggested for minimal renovation, major renovation and new construction of these kinds of buildings. An overall plan for a more habitable location of poet facilities was suggested. The behavior setting survey technique in shortened form proved useful in this study. Suggestions for future research in testing habitability guidelines were made.

SR 76-11 OBSERVATIONS ALONG THE PIPELINE HAUL ROAD BETWEEN LIVENGOOD AND THE YUKON RIVER.

Berg, R.L., et al, Oct. 1976, 73p., ADA-033 380, 7 refs. Smith. N. 32-1247

ROADS, SLOPE STABILITY, GROUND ICE, VEGETATION.

VEGETATION.

Periodic observations over a six-year period along the TAPS Road have been evaluated with respect to construction and slope stabilization techniques in ice-rich roadway cuts and embankment subgrades. Lateral drainage ditches of sufficient width to handle construction excavation equipment, along with near-vertical slope cuts with hand-cleared tops equal in width to one and one-half times the height of the cuts, significantly enhance natural processes of slope stabilization. Right-of-way clearing limited to the toe of embankment fill slopes minimizes subsidence of the roadway and its shoulder slopes. In extremely ice-rich soil cuts, the seeding of the slopes ahould not be attempted until late in the first thaw season for best results. Natural late in the first thaw season for best results. Natural swoody growth can be expected to have a substantial stabilizing effect after five or six thaw seasons but could be accomplished sooner by planting tree seedlings. Attempts to stabilize ice-rich cut slopes with applications of insulation are not very effective and seem to prolong the natural stabilization process.

OPERATIONAL REPORT: 1976 USACRREL-USGS SUBSEA PERMAFROST PROGRAM BEAUFORT SEA, ALASKA.

Sellmann, P.V., et al, Oct. 1976, 20p., ADA-032 440,

Lewellen, R.I., Ueda, H.T., Chamberlain, E.J., Blouin, 32-1248

OFFSHORE DRILLING, LOGISTICS, SEA ICE, SUBSEA PERMAFROST.

SUBSEA PERMAPROST.

During the spring of 1976, three holes were drilled offshore in the Prudhoe Bay area using the sea ice cover as a drilling platform. The objectives of this program were to obtain samples and subsurface information to aid in quantification of the engineering characteristics of permafrost benesth the Beaufort Sea as well as to conduct supporting thermal and geological studies. The results of the drilling and related investigations are being used in conjunction with data from other subsex permafrost projects to develop maps and models for the prediction of permafrost occurrence in this offshore environment. The project also provides a means of testing drilling, sampling, and in-situ measurement techniques in an offshore setting where material types and sea ice conditions make acquisition of undisturbed samples extremely difficuit. This report documents the operational aspects of the spring 1976 field study; subsequent reports will cover the technical and research results.

ENVIRONMENTAL ANALYSES IN THE KOOTENAI RIVER REGION, MONTANA. McKim, H.L., et al, Nov. 1976, 53p., ADA-033 500,

Gatto, L.W., Merry, C.J., Brockett, B.E., Bilello, M.A., Hobbie, J.E., Brown, J. 32-1255

J2-1233 CLIMATOLOGY, RESERVOIRS, ICE COVER, LIMNOLOGY, SPACEBORNE PHOTOGRAPHY, UNITED STATES—MONTANA—KOOTENAI

UNITED STATES—MONTANA—KOOTENAI RIVER.

The purpose of this investigation was: 1) to compile and analyze climatic data for the past 10 years from all available weather observing stations in the East Kootenai River Basin, 2) to analyze changes in ice and anow cover, and turbidity and plankton blooms on Lake Koocanusa, 3) to assess the present limnology of Lake Koocanusa and the potential for water quality problems, especially eutrophication, and 4) to demonstrate the reliability of the LANDSAT Data Collection Platform (DCP)-Martek Water Quality Monitor system for sequisition of data from a remote site. Results of the investigations indicate that the Kootenai region is about twice as cold as the Libby region in winter, and that reservoir ce first forms along the shore in the northern region in late November and in the southern part in mid-December, with total freeze-over usually occurring 2 to 4 weeks later. Ice break-up in the northern sections usually occurs 1-3 weeks later than in southern areas; average annual snowfall is 42 to 144 in., with ice thickness and snowfall varying with relief. Variations in areal distribution of snow within the basin and ice cover on the reservoir were observable for periods from January to October 1973, and reservoir furbidity was observed to increase south of Elisworth and Stenerson Mountains. Low algal productivity observed was due to the algae being circulated most of the time below the depth of 1% light and due to high turbidity. The DCP-Marrek system operated well and reliable data were received while the system was located in the pool above Libby Dam and downstream below the dam. Brief interruptions in data transmissions occurred in April, when the Martek sensor showed a few minor inconsistencies, but the system demonstrated the feasibility of this technique for data acquisition from remote sites.

SR 76-14 NOTES ON CONDUCTING THE BEHAVIOR SETTING SURVEY BY INTERVIEW METHOD. Ledbetter, C.B., Nov. 1976, 33p., ADA-062 448, 17

ENVIRONMENTS, HUMAN FACTORS, MILITARY FACILITIES.

Practical guidelines for conducting the behavior setting survey by interview method are presented. This training manual for the layperson describes the data, survey forms and interview

PATE AND EFFECTS OF CRUDE OIL SPILLED ON PERMAFROST TERRAIN. FIRST YEAR PROGRESS REPORT.

Collins, C.M., et al, Nov. 1976, 18p., ADA-034 140,

Deneke, F.J., Jenkins, T.F., Johnson, L.A., McFadden, T., Slaughter, C.W., Sparrow, E.B. 32-1257

OIL SPILLS, SOIL TEMPERATURE, VEGETA-TION, PERMAFROST.

TION, PERMAFROST.

The long-term effects and ultimate fate of crude oil spilled on permafrost-underlain tundra is the subject of this study. The project involves two experimental oil spills of 2,000 gallons (7,570 liters) each on 500 sq m test plots near Fairbanks, Alaska. A winter spill, discussed in this progress report, took place in February 1976. Another spill will take place at the peak of the growing season in the summer. This allows conditions prevailing during these climatic periods to be studied as to their effect on oil spills, and makes it possible to study the reaction of the spilled oil to these temperature extremes. The spill discussed in this report was designed to simulate a real pipeline leak, and was large enough to approach reality while remaining within the limits of logistical capabilities. Monitoring of the spill and control lots includes: oil movement, temperature regime, biological effects, microbiological changes, permafrost impact, and chemical degradation of the oil.

UTILITY DISTRIBUTION SYSTEMS IN SWEDEN, FINLAND, NORWAY AND ENGLAND.

Aamot, H.W.C., et al, Nov. 1976, 121p., ADA-035
088, Bibliography p.116-121.

McFadden, T.

UTILITIES, SEWAGE DISPOSAL, ELECTRICITY, HEATING, WATER SUPPLY, SCANDINAVIA, UNITED KINGDOM.

The study reports on new developments and special problems or solutions in water distribution systems, sewage and solid waste transport systems, heat distribution systems and electric transmission systems. Cold weather considerations are highlighted. For water and sewage systems, the use of ductile iron and plastic materials for pipes is reported. The use of heating, insulating or shielding of the pipes for frost protection is of interest. Some developments in tunneling technology were identified. Pneumatic solid waste collection and vacuum sewage collection represent new developments. For heat distribution, the many different types of pipe and insulation systems used are described. Good moisture control in insulation is emphasized. Developments in long distance heat transmission are discussed. With electric distribution, the use of self-supporting serial cables is a new development. With transmission, problems of icing and countermeasures are discussed. Cold weather considerations are ssion systems.

ENERGY CONSERVATION IN BUILDINGS. Ledbetter, C.B., Dec. 1976, 8p., ADA-034 141, 3 refs.

HEATING, BUILDINGS, CONSERVATION.

This report scans current building designs and describes, for the layman, ways that buildings could be designed for improved energy consumption. Topics of building design addressed are insulation, thermal bridges, ventilation, orientation, lighting, windows, and solar heat.

IMPROVED MILLIVOLT-TEMPERATURE CONVERSION TABLES FOR COPPER CON-STANTAN THERMOCOUPLES. 32F REFER-ENCE TEMPERATURE,

SELECTED EXAMPLES OF RADIOHM RESISTIVITY SURVEYS FOR GEOTECHNICAL EX-PLOBATION.

Hoekstra, P., et al, Jan. 1977, 16p., ADA-035 761, 20

Sellmann, P.V., Delaney, A.J.

GEOPHYSICAL SURVEYS, ELECTRICAL RESIS-TIVITY, PERMAPROST INDICATORS, GRAV-

Measurements of ground resistivity using radio wave techniques have been made in support of several geotechnical projects. Examples of surveys conducted for locating and evaluating gravel deposits, for delineating permafrest, and for extrapolating subsurface information between drill holes are used to illustrate some advantages of ground and airborne surveys using this method.

CREEL ROOF MOISTURE SURVEY, PEASE AFB BUILDINGS 33, 116, 122 AND 205. Korhonen, C., et al, Jan. 1977, 10p., ADA-035 762. Tobiasson, W., Dudley, T.

32-1276 ROOFS, MOISTURE, INSULATION, INFRARED

EQUIPMENT.

EQUIPMENT:

Four building roofs at Pease AFB were surveyed with a hand-held infrared camera to detect wet insulation. Areas of wet insulation on these roofs were marked with spray paint, and 3-in-diam core samples of the built-up membrane and insulation were taken to verify wet and dry conditions. Flashing defects are considered responsible for most of the wet insulation uncovered in this survey. Recommendations for maintenance, repair, and replacement were developed from the infrared surveys, core samples and visual examinations.

32-1278
PIPELINES, MAINTENANCE, CONSTRUCTION, UNITED STATES—ALASKA.
This report is intended to provide a background for the analysis and evaluation of new pipelines being built in cold regions. Topics discussed include the initial design, construction, testing, operation and maintenance of, and modifications to the 8-in. pipeline from the deep water port of Haines to military installations at Fairbanks, Alaska. The 626-mile multi-product pipeline began operation in 1956. The results of a corrosion survey completed in 1970 indicated that extensive renovation would be required to continue operations, and the section from Haines to Eielson Air Force Base was closed in 1973.

32-1279

ENVIRONMENTAL TESTS, HUMAN FACTORS ENGINEERING, BUILDINGS.

ENGINEERING, BUILDINGS.

A demonstration of Barker's K-21 test for identifying and differentiating behavior settings is presented as a means of diagnosing problems in an office environment. For didelines for rearranging the layout of an organization's offices are developed that could also be used for architectural programming for a new building if the organization were to be relocated. As an instructional program, the demonstration presented here shown how to conduct the K-21 test in order to analyze problems concerning behavior setting boundaries or conflicts between behavior settings.

SYMPOSIUM: GEOGRAPHY OF POLAR COUNTRIES; SELECTED PAPERS AND SUM-

Brown, J., ed, Mar. 1977, 61p., ADA-038 379, In English and Russian. Numerous refs. For selected papers see 32-1302 through 32-1306. 32-1301

LAND DEVELOPMENT, ENVI-RONMENTAL PROTECTION.

The symposium on Geography of Polar Countries held in Leningrad 22-26 July 1976 as part of the XXIII International Geographical Congress consisted of three seasions: (1) Polar environment, natural resources, their exploration and exploitation; (2) Past, present and future economic developments in the polar regions; (3) Polar environment protection. This report presents the full test or extended summaries of anumber of the U.S. pepers, and English and Russian summaries of the Soviet contributions related to environmental protection. of the Soviet contributions related to environmental protection. The papers and summaries presented in this report reflect the participation of members and of the joint US-USSR environmental protection agreement project, Protection of Northern Boosystema.

The U.S. papers deal with land use planning to mitigate environmental impact: the impact of resource development on natives, fish and wildlife, and permafrost, the impacts of pipelines and roads on the environment, and computer modeling to simulate terrain modification due to man's activities. The Soviet summaries deal with subjects of properties and changes in arctic and subarctic flora, treeline, and permafrost, and methods of predicting changes in the environment.

COMPUTER ROUTING OF UNSATURATED FLOW THROUGH SNOW.

Tucker, W.B., et al, May 1977, 44p., ADA-040 121. Colbeck, S.C. 32-1313

SNOW COVER, WATER FLOW, SNOWMELT, COMPUTER PROGRAMS.

COMPUTER PROGRAMS.

Computer programs for routing the vertical movement of water through snow have been developed. The shock front is dependent on surface melt taking place now as well as the antecedent flow in the snow, usually a function of the nature of the flow for the previous day. One program, designed to accommodate actual surface melt data, has the shilly to handle complicated input profiles such as when melt is erratic on a cloudy day, creating such complexities as intersecting shock fronts. Another program, designed for rapid simulation purposes, approximates a simple surface input with a function, in this case a sine wave. This function is easily changed, sllowing a variety of conditions to be assessed, although only one shock front is accommodated. Error analysis and some applications of the programs are presented.

DEMONSTRATION OF BUILDING HEATING WITH A HEAT PUMP USING THERMAL EF-

32-1314
HEAT RECOVERY, HEATING, BUILDINGS, COST ANALYSIS, HEAT PUMPS.
This report describes efforts made to recover waste heat and to reuse it to heat a building. A heat pump, which is a refrigeration device, was operated to provide building heat and to demonstrate both economic benefits and energy savings possible with this type of heating system. Heat pump fundamentals and system design considerations supplement the report of this demonstration project. Operational characteristics were monitored and are reported. A 25% reduction in heating costs was observed compared with an oil-fired system. The author recommends that the minimum coefficient of performance should be 3.4 for a cost effective, energy-conservative heat pump heating system.

SR 77-12 LABORATORY STUDIES OF COMPRESSED AIR SEEDING OF SUPERCOOLED FOG. Hicks, J.R., et al, May 1977, 19p., ADA-040 633, 3

Rice, R.C., Jr. 32-1315

SUPERCOOLED SUPERCOOLED FOG, CLOUD SEEDING, LABORATORY TECHNIQUES.

Some 400 tests were conducted in the CRREL cold cloud chamber to determine the combination of air pressure nozzle design that yielded the maximum production of ice crystals in a supercooled fog. It was found that some 0.22 cu m/min of sir which was compressed to 517 kPa is needed to be effective for clearing a supercooled fog.

STAKE DRIVING TOOLS: A PRELIMINARY SURVEY.

Atkins, R.T.

32-1316 ANCHORS, FROZEN GROUND, DRILLS, PILE DRIVING, HAMMERS.

DRIVING, HAMMERS.

This report gives results of a study of four commercial breaker-rock drills, a prototype hydraulic stake driver-retriever and a prototype propellant-actuated hammer which were evaluated for driving anchors into hard frozen ground. The tests found that commercial breaker-rock drills can be used without modification to drive standard military GP-112/G and GP-113/G stakes into frozen ground. The study revealed that while the hydraulic stake driver would require further development to increase in reliability, it could drive the above stakes into frozen ground. The propellant-actuated stake driver was found incapable of driving stakes into hard frozen ground and was not considered worthy of further development as a stake driver.

Jenkins, T.F., Murrmann, R.P. 32-1319

EXPLOSIVES, IMPURITIES, VAPOR PRESSURE,

EXPLOSIVES, IMPURITIES, VAPOR PRESSURE, CHEMICAL ANALYSIS.

A number of domestic and foreign military TNT samples were analyzed by a gas chromatographic headspace technique. The method allowed the determination of the vapor pressure of TNT and the partial pressures of several associated impurities over a 2 to 32C temperature range. A major volatile impurity in all U.S. military TNT samples was 2,4-dinitrotoluene, which had a partial pressure 1 to 2 orders of magnitude higher than the vapor pressure of TNT. The experimental data followed a Clausius-Clapeyron temperature dependence for the vapor pressure of TNT, and the partial pressure of DNT was related to its concentration in the solid by a Henry's constant. Age and source of the TNT were found to have little or no influence on these relationships. The reasons for finding a relatively high DNT partial pressure are discussed, as is its implication for TNT detection by trace gas methods.

INSTALLATION OF LOOSE-LAID INVERTED ROOF SYSTEM AT FORT WAINWRIGHT, ALASKA.

Schaefer, D., June 1977, 27p., ADA-041 574, 11 refs. 32-1321

ROOFS, INSULATION, COST ANALYSIS.

In the summer 1971 the Corps of Engineers replaced the roof on Building 1053 at Ft. Wainwright, Alaska, with a loose-laid inverted roof system. This roof system was selected to permit an evaluation of its performance and potential suitability for general use in Corps construction. The installation of the roof also permitted an analysis of its construction costs and a record of the construction procedures. Costs were identified in terms of costs of the its construction costs and a record of the construction procedures. Costs were identified in terms of costs of the materials used and the number of man-hours required. For the analysis, the job was broken down into four phases:
1) removal of the existing roofing material and preparation of the deck; 2) application of a surface of plywood decking;
3) placement of the butyl membrane and installation of flashings; and 4) placement of the insulation and bellast pavers. The results show that the installation time requirements commerce favorable with these of conventional built. ments compare favorably with those of conventional built-up roofs but the butyl membrane and the pavers cause higher material costs. Advantages are in the maintainability of the roof system and in its increased life expectancy.

SOIL ANALYSIS, SOIL CHEMISTRY, SLUDGES. PLANTS (BOTANY), VEGETATION.

PLANTS (BOTANY), VEGETATION.

A field study was conducted to assess the effects of sewage studge and lime on the revegetation and reclamation of acidic (pH 3.0) and infertile dredge soils. Sewage studge at 100 metric tons/ha metric study has and lime at 25 metric tons/ha were applied during the summer of 1974 on a seven hectare site and plowed into the soil to a depth of 20 cm. Soils were sampled 20 months after studge incorporation at three depths, 0-20, 20-40, and 40-50 cm within the studged and control areas. A total of 29 grass treatments, containing grasses seeded alone or in combinations, were also evaluated and screen grass types analyzed for mineral composition. Comparisons between the studged and control areas in the layers from 0-20 cm and below 20 cm were made in terms of changes in soil and plant chemistry, plant utilization of soil minerals, plant adaptability and vigor, and eventual resulting vegetative cover. resulting vegetative cover

UNCONFINED COMPRESSION TESTS ON SNOW: A COMPARATIVE STUDY. Kovacs, A., et al, July 1977, 27p., ADA-062 445, 21

refs.

Michitti, F., Kalafut, J. 32-4357

SNOW COMPRESSION, COMPRESSIVE STRENGTH, TESTS.

STRENGTH, TESTS.

Results of unconfined compression tests performed on snow from Camp Century, Greenland, using a new self-aligning platen system are compared with tests using a more conventional platen system. The average unconfined compressive test strength was 42% higher for samples tested on the new platen system provides for better sample alignment and therefore a more uniform load distribution applied to the ends of the sample. The higher strength values obtained with the new platen system are considered more representative of the unconfined compressive strength of the snow tested.

SP 77-21 INVESTIGATION OF SLUMPING FAILURE IN AN EARTH DAM ABUTMENT AT KOTZEBUE. AT.ASKA

McFadden, T.

RESERVOIRS, EARTH DAMS, FROZEN GROUND TEMPERATURE, SETTLEMENT (STRUCTURAL), SUBSIDENCE.

A slumping failure on the upstream side in one area of the water supply reservoir at Kotzebue, Alaska, was investigat-ed. Seven 80-ft (24.4-m) thermocouple strings were em-placed in the dam shutment, and an additional four thermocouple strings were installed behind the dam, extending to a depth of 95 ft (28.9 m) below the bottom of the reservoir. All thermocouples indicated below freezing temperatures at All thermocouples indicated below irecams temperatures at their respective positions. These measurements combined with the drill logs indicate that neither the dam nor the abutment is in immediate danger of failure, but that steps must be taken to stop the abutment area. Recommendations are given to accomplish

Itagaki, K. 32-1355

CUBIC ICE, ICE PHYSICS, ICE CRYSTAL STRUCTURE, TEMPERATURE EFFECTS, ICE

A series of sharp skewed internal friction peaks were observed during warming of single-crystal ice after cooling below - 120C (133K), the -ubic-hexagonal transition temperature. The peaks were higher when the strain amplitude was lower.

Since handling and annealing strongly affect the occurrence of the skewed peaks, those peaks are probably related to the stacking fault process in hexagonal-cubic transition. SR 77-24

BRAZIL TENSILE STRENGTH TESTS ON SEA ICE: A DATA REPORT.

SEA ICE, IMPACT STRENGTH, PENETRATION TESTS.

In March 1970 drop penetrometer tests in sea ice were made by Sandia Laboratories for the U.S. Coast Guard. In support of this study, properties of the sea ice penetrated were measured. The data collected included ice temperature, salinity, brine volume, density and Brazil tensile strength versus depth. The data are presented in this report in both tables and graphs as a permanent data source.

SP 77-25 SOLVING PROBLEMS OF ICE-BLOCKED DRAINAGE FACILITIES. Carey, K.L., Aug. 1977, 17p., ADA-044 994, 4 refs. 32-1357

32-1357 SURFACE DRAINAGE, ICE CONTROL, HEAT-ING, SUBSURFACE DRAINAGE.

ING, SUBSURFACE DRAINAGE.

The report summarizes several processes for ice formation and blockage in culverts, ditches, and subsurface drains. Solutions to ice blockage problems involve ice prevention and ice control, usually the latter. In some cases, culverts can be closed, leading to intentional ponding and storage of ice. Alternatively, flow can be maintained in culverts by heating them electrically, with steam, or with oil-burner heaters. Ditches can also be heated, but it is usually more effective to widen them to provide more storage space for ice, or to install insulating covers. Subsurface drain outlets can be heated, protected with insulating covers, or partially blocked to prevent cold air entry. Ground seepage that forms ice is successfully controlled using ice fences. Design changes, such as more and larger drainage structures, staggered culverts, and channel modifications, are discussed. SER 77-26

SR 77-26 INFRARED THERMOGRAPHY OF BUILD-INGS: QUALITATIVE ANALYSIS OF FIVE BUILDINGS AT RICKENBACKER AIR FORCE

AIRBORNE SPECTRORADIOMÉTER DATA
COMPARED WITH GROUND WATER-TURBIDITY MEASUREMENTS AT LAKE POWELL,
UTAH: CORRELATION AND QUANTIFICATION OF DATA.

Merry, C.J., Sep. 1977, 38p., ADA-044 793, Bibliography p.26-29.

WATER CHEMISTRY, TURBIDITY, LIGHT TRANSMISSION, SPECTRORADIOMETERS, AERIAL SURVEYS, UNITED STATES—UTAH— LAKE POWELL

LAKE POWELL.

The objective of this study is to correlate and quantify the airborne spectroradiometer multispectral data to ground truth water quality measurements obtained at Lake Powell, Utah, during 1975. A ground truth water sampling program was accomplished during 9-16 June 1975 for correlation to an aircraft spectroradiometer flight. Fleid measurements were taken of percentage of transmittance, surface temperature, pH and secchi disk depth. Also, percentage of light transmittance was measured in the laboratory for the water samples. In addition, electron micrographs and suspended sediment

concentration data were obtained of selected water samples located at Hite Bridge (Mile 171), Mile 168, Mile 150 (along the Colorado River main channel) and Builfrog Bay (Mile 122). Airborne spectroradiometer spectra were selected which correlated to the same test sites.

SR 77-29 INFRARED THERMOGRAPHY OF BUILD-INFS: QUALITATIVE ANALYSIS OF WINDOW INFILTRATION LOSS, FEDERAL OFFICE BUILDING, BURLINGTON, VERMONT. Munis, R.H., et al, Sep. 1977, 17p., ADA-044 942. Marshall, S.J. 32,1360.

32-1360

INFRARED PHOTOGRAPHY, THERMAL DIFFUSION, BUILDINGS, HEAT LOSS, WINDOWS. FUSION, BUILDINGS, HEAT LOSS, WINDOWS. An interior, infrared thermographic survey of single-pase, aluminum-frame, projected windows was performed to pinpoint locations of excessive infiltration. Infrared thermographic inspection accomplishes this more quictly and more accurately than conventional techniques of studying window infiltration. This report presents 32 thermograms and photographs which in many cases dramatically illustrate infiltrations around the mullion, along the top opening cracks, and under the frame/sill interfaces. Poor glazing seals were easily detected and the exact points of glass/frame leakages were pinpointed. Plumes of warn air on the window glass, rising from the convectors, were dramatically captured by the infrared camera system. In several cases, the plumes were noted 12 ft. above the convectors on the top window panels. Heat loss from the convectors was noted through the walls of the building in thermograms taken from the outside. Several recommendations were prepared for the General Services Administration, owner of this Federal Office Building in Burtington, Vermont.

32-1361

EXCAVATION, SUBGRADES, PAVEMENT RASES

BASES.

Recycling of paving materials is currently gaining acceptance as a means of economic savings in pavement reconstruction or rehabilitation. Pavements having low serviceability indices due to surface irregularities such as cracks, bumps, spalling, potholes, etc., may be broken up to meet specified granular base course gradation requirements and reused as a base for the new surface. The USACREL developed a permatirost excavating attachment for heavy buildozers and a prototype test rig was constructed.

Tests were conducted on frozen soils, gravels, and lodge.

Tests were conducted on frozen soils, gravels, and lodge.

Tests were conducted on frozen soils, gravels, and lodge.

Tests were conducted many first of the soil of the sections in a CRREL test facility. The resultant processed material did meet Corps of Engineers bese course gradation requirements. The machine can process 120 square ft of pavement structure per minute to a depth of 12 inches. The most uniformly graded material was obtained at a drum speed of 15 revolutions per minute.

Once the pavement structure is broken down from the solid mass (asphalt concrete pavement), the machine does not further break down or pulverize the aggregate.

A minor amount of dust was evident during the operations, but no refinements are recommended.

SR 77-31 EFFECTS OF LOW GROUND PRESSURE VEHI-CLE TRAFFIC ON TUNDRA AT LONELY, ALAS-

AIR CUSHION VEHICLES, TRACKED VEHICLES, TUNDRA VEGETATION, VEHICLE WHEELS, ENVIRONMENTAL IMPACT, DAMAGE, PATTERNED GROUND, SOIL MOISTURE.

Traffic tests were conducted with two low pressure tire Rolligon-type vehicles and a small, tracked Nodwell with minimal load for 1, 5, and 10 vehicle passes on relatively dry tundra near Lonely, Alaska. The traffic impact was limited to compression of the vegetation and the organic mat and a maximum terrain surface depression of several cm, with no shearing or disaggregation of the mat. SR 77-32

AERIAL PHOTOINTERPRETATION OF A SMALL ICE JAM.
DenHartog, S.L., Oct. 1977, 17p., ADA-045 870.

32-1362 ICE JAMS, AERIAL SURVEYS, PHOTOINTER-PRETATION.

Aerial photos of a small ice jam on the Pemigewasett River near Plymouth, New Hampshire, were taken three days after the jam and compared with photos taken after the ice went out. The winter photos show a marked and sudden decrease in floe size apparently indicative of faster and longer movement of the ice. The spring photos show a number of shallows and obstructions that apparently had no effect on the ice movement. It is concluded that this jam was caused by a change in slope and subsequent reduction in velocity.

LAND TREATMENT OF WASTEWATER AT WEST DOVER, VERMONT.

nizoun, J.R., Oct. 1977, 24p., ADA-046 300, 12 refs. 32-1363

WASTE DISPOSAL WATER TREATMENT, SEWAGE TREATMENT.

SEWAGE TREATMENT.

A general description of a westewater land treatment system located in a "cold temperate" climatic region is given. The winter season average daily design flow is almost double that of the summer-hall season (0.55 MGD vs 0.30 MGD). Wastewater is sprayed on a forested knoll after it receives secondary biological treatment. The system is operated during the winter when the ambient air temperature is as low as 10F. Spray nozzles have been developed that ensure rapid drainage of the spray laterals after each spray cycle and, therefore, prevent their freezing.

SMALL COMMUNITIES RESULT IN GREATER SATISFACTION: AN EXAMINATION OF UN-DERMANNING THEORY.

Ledbetter, C.B., Nov. 1977, 15p., ADA-046 817, 3

refs. 32-1367

HUMAN FACTORS, THEORIES.

HUMAN FACTORS, THEORIES.
Roger Barker's undermanning theory states that the smaller an organization, the greater the degree of undermanning, resulting in greater inhabitant satisfaction. This theory is examined using the National Opinion Research Center's General Social Survey for 1974. Two groups of survey variables were dichotomized and net transmittances or coefficients of correlation for the system were determined. Two groups of variables were chosen: objective groups, such as age and income, and subjective ones, such as sociability and job satisfaction. The only positive correlation found was that people residing in small communities are more satisfied with their community than are people who live in large communities. Only a small portion of this is explained by the degree to which small town inhabitants are satisfied with their financial situation.

UTILIZATION OF SEWAGE SLUDGE FOR TER-RAIN STABILIZATION IN COLD REGIONS. Gaskin, D.A., et al, Nov. 1977, 45p., ADA-047 368. Hannel, W., Palazzo, A.J., Bates, R.E., Stanley, L.E.

32-1368

32-1368
SOIL STABILIZATION, SLUDGES, EROSION CONTROL, SEWAGE, VEGETATION.
A terrain stabilization research/demonstration site was constructed in May 1974 at Hanover, New Hampshire, to investigate various combinations of physical, chemical and biological techniques for terrain stabilization in cold regions. Fourteen test plots (10 x 40 ft) with individual 350 gal tanks to collect aediment were installed on a 16 deg slope. These 14 test plots were to examine the effectiveness of sewage sludge and primary effluent on terrain stabilization in cold regions. In 13 of the 14 plots the variables studied were nutrient source (fertilizer, sludge, and primary wastewater), moisture (trrigated and nonirrigated), erosion control material (jute netting, straw tacked with a tacking compound), no erosion control material and vegetation (three grasses and two legumes). The control plot was left bare of seed,

fertilizer and erosion control material for comparison. A 20,000 sq ft area adjacent to the 14 plots was installed for general testing of various combinations of tacking chemicals, plastic netting, straw, and wood fiber mulch. In general, all treatments with the exception of two plots were effective in reducing soil lose in comparison with the control which had a loss of 34,531 lb of soil (dry weight) on a per acre basis.

FINITE ELEMENT MODEL OF TRANSIENT HEAT CONDUCTION WITH ISOTHERMAL PHASE CHANGE (TWO AND THREE DIMEN-SIONAL).

Guymon, G.L., et al, Nov. 1977, 167p., ADA-047 369. Hromadka, T.V., II.

32-1369

THERMAL CONDUCTIVITY, MATHEMATICAL MODELS, COMPUTERIZED SIMULATION, FROZEN GROUND MECHANICS, COMPUTER

PROGRAMS.

The partial differential equation for transient heat conduction is solved by a finite element analog using a quadratic weighting function for the discretized spatial domain. The transient problem is solved by the Crank-Nicolson approximation. Two dimensional and three dimensional models incorporated in the same computer program are presented. The finite element method is reviewed, assumptions and limitations upon which the model is based are presented, and a complete derivation of the system analog is included. Certain problems can only be modeled as a three dimensional system, e.g., thaw degradations around roadway culverts, embankment dams on permatrost where dam length is short relative to dame on permatrost where dam length is short relative to dam width, and thaw and freezeback under buildings. In most cases, however, the more economical two dimensional model can be used. Numerical tests of both models have been accomplished but field verification has not been attempt-ed. A user's manual and a FORTRAN IV computer listing of the program are presented.

Bennett, F.L., Nov. 1977, 41p., ADA-048 987, 2 refs.

COLD WEATHER CONSTRUCTION, BUILD-INGS, HEATING.

INGS, HEATING.

Nine building construction projects, whose total area exceeds one half million square feet, were under construction in Fairbanks, Alaska, area during the winter of 1976-77. These projects were studied to determine the methods used for providing temporary enclosures and temporary building heating during the construction process. The types of construction activities underway at various temperature conditions are reported, and a record of temperature variations in the buildings under construction is discussed. Both black and white and color photo documentation was developed, and several black and white photographs are included in this report. SP 77-40

WINTER EARTHWORK CONSTRUCTION IN

UPPER MICHIGAN. Hass, W.M., et al, Nov. 1977, 59p., ADA-049 052, 5 refs. Sec also 32-293.

Alkire, B.D., Dingeldein, J.E. 32-2698

EARTHWORK, SUBGRADE PREPARATION, COLD WEATHER CONSTRUCTION, FROZEN GROUND.

Winter earthwork construction was observed in three counties in Michigan's Upper Peninsula during the 1975-76 season. In all cases, construction methods are used which exclude frozen soil from the central core of the embankment, with frozen soil permitted in the outer slope zone. While all projects were technically successful, construction was halted and which the projects were technically successful, construction was halted. all projects were technically successful construction was halted in early February on one project because it was uneconomical for the contractor to continue. On another project, the contractor successfully exploited soil freezing to form stable amonth haul roads for his scrapers. Most of the work consisted of raising the grade of existing roads by 18 inches of non-frost-succeptible soil to minimize frost heaving and loss of bearing capacity. This winter activity resulted in better utilization of county equipment and work crews.

1977 CRREL-USGS PERMAFROST PROGRAM BEAUFORT SEA, ALASKA, OPERATIONAL RE-

BEAUTY STATES AND STATES AND STATES AND A-048 985, 11 refa. See also 32-1248 (SR 76-12, ADA-032 440). Chamberlain, B.J., Ueda, H.T., Blouin, S.E., Garfield, D.E., Lewellen, R.I.

OFFSHORE DRILLING, DRILL CORE ANALYSIS, SUBSEA PERMAFROST, BOTTOM SEDI-MENT, TEMPERATURE MEASUREMENT.

MBASUREMENT:
During the spring of 1977 soil samples were obtained in
the Prudhoe Bay area from one hole drilled on land and
five holes drilled offkhore. The study is a continuation
of the wrogram started the previous season to ramine the
engineering chara-ceristics and properties of permafrost under
the Beaufort Sea. Emphasis was placed on establishing
the range of thermal and physical properties found in this
geological setting, which is thought to be common to much

of the eastern Alaska coastal zone. Twenty-seven probe aites were selected to determine local engineering properties and temperature conditions, and to aid in interpreting the lithology between the drill holes. Core drilling information from some of the probe sites was used as control for interpreting the probe records. Deep thermal and geological information was obtained from the drill sites by the USGS personnel participating in the study. Maximum drill hole depth was 618 or (225 8) and maximum constraints death was was obtained from the drill sites by the USGS personnel participating in the study. Maximum drill hole depth was 68.5 m (225 ft) and maximum penetration depth was 15 m (50 ft). The probe temperature data indicated the presence of permafroat in all holes. Probe penetration resistance measurements helped to delineate shallow, iconded zones, some of which may have been only seasonal. In the core study, frozen sediments were found in only one hol : approximately the 29.6-m (97-ft) depth. Fine-grained iments were more common than course-grained material: and showed general increase in thickness with increasing distance from shore. The only departure from the material. and showed general increase in thickness with increase ing distance from shore. The only departure from the previous year's field drilling techniques was the use of larger diameter, thick-walled casing and an air-operated casing driver. The probe equipment and techniques employed, however, represented a significant improvement over the prototype equipment used in 1976.

SR 77-42 GROUTING OF SOILS IN COLD ENVIRON-MENTS: A LITERATURE SEARCH.

Johnson, R., Dec. 1977, 49p., ADA-049 436, 52 refs.

GROUTING, ADMIXTURES, SOIL STRENGTH. A literature search was undertak... to collect information on grouting of soils as related to low temperature environment, 40 F and below. This report reviews existing literature and the state-of-the-art on conventional grouting engineering methods and materials to seek which may be used in thawed or dry, forcen ground and to establish the need of new methods and techniques where conventional grouting methods fail

OIL SPILLS, DAMAGE, CHEMICAL REACTIONS, FROZEN GROUND, ENVIRONMEN-TAL IMPACT, VEGETATION.

TAL IMPACT, VEGETATION.

This spill was compared with one that took place in February 1976 (reported upon in the first annual progress report). Oil moved downslope at a much faster rate during the summer spill than during the winter spill. In the winter he oil cooled and pooled rapidly. The summer spill covered approximately one-third more surface area than did the winter spill in the final configuration, even though the two spills were of almost identical volume. Increases in microbial populations and activities during the months following the spill were evident. Increased counts of bacteria, yeasta, denitrifying bacteria, and petroleum-degrading bacteria following the spills were particularly evident. Analysis of oil decomposition using gas chromatography techniques indicated that the low molecular weight fractions, methane and etane, were lost almost immediately after the spill each case. Fractions in the C3 to C9 range were reduced aignificantly in two months and were nearly zero at the end of five months. An obvious adverse effect on vegetation was noted in both spills. Biological damage from the summer spill appeared to exceed that from the winter spill. SR 78-01

RECOMMENDATIONS FOR IMPLEMENTING ROOF MOISTURE SURVEYS IN THE U.S. ARMY.

U.S. Army CRREL/WES/FESA Roof Moisture Research Team, Aug. 1978, 8p., ADB-031 978L, Distribution limited to U.S. Government agencies only. 33-1534

MOISTURE METERS, ROOFS, IN

Nuclear, infrared, capacitance, microwave and impulse radar methods for non-destructively detecting moisture in roofs

were evaluated. No system was reliable enough by itself or by cross-checking with another system to eliminate the need for a few core samples of membrane and insulation to verify findings. Airborne infrared surveys are a cost-effective way of reconnoitering numerous roofs at a major installation. However, follow-up on-the-roof surveys are necessary. Of the several grid techniques examined, nuclear surveys were the most reliable. Hand-held infrared surveys were the most reliable. surveys were the most reliable. Hand-held infrared surveys are the most accurate on-the-roof method studied. Although an infrared camera costs significantly more than a nuclear meter (\$25K vs. \$3K), infrared surveys can be conducted more rapidly. Since the Army has numerous roofs to survey, infrared surveys appear to be the most cost-effective method. For reasons of continuity, accuracy and economy, the Army should establish its own capability to survey roofs for moisture. Implementation should not be at the installation level. A centralized team of roof moisture surveying specialists, skilled in operating infrared equipment but, more importantly, skilled in roofing technology, should be established. The team should both conduct and contract for airborne and on-the-roof infrared surveys. The CRREL/-WES/FESA roof moisture research group has initiated development of training aids for use by such a team.

LARGE MOBILE DRILLING RIGS USED
ALONG THE ALASKA PIPELINE.
Sellmann, P.V., et al, Mar. 1978, 23p., ADA-053 536.

Mellor, M. 32-3539

PIPELINES, DRILLING, UNITED STATES ALASKA.

The requirement for installing more than 70,000 vertical support members along elevated sections of the Alaska Pipeline resulted in an extremely large drilling program. Several large drilling units, some specially designed, including rotary (auger), percussive, and combination rotary-percussive units, were selected for this job. This selection of equipment and techniques provided the potential to drill in all conceivable material types. An examination of these drills in the and techniques provided the potential to drill in all conceivable material types. An examination of these drills in the field, together with product literature, provided some insight into the characteristics of these drills compared with other commercially available drilling units. The pipeline drilling program provided a major impetus for design and development of new equipment in the area of large rotary-percussive and percussive drilling units. The pipeline drills in general showed sound design characteristics in weight, power, thrust, torque, and speed. Many of the auger boring heads could benefit from improvements in shape, angles, cutter position, and in consideration of "the center of the hole" problem. Need for work in this area was indicated by drilling rates, as well as by noticeable improvements in some augers following contractors' field modifications.

RESERVOIRS, REMOTE SENSING, SNOW WATER EQUIVALENT, LANDSAT, FLOODS, WATER SUPPLY, COMPUTER APPLICATIONS. A preliminary analysis of Landast digital data using the NASA GISS computer algorithms for a February 11 scene of the upper St. John River Basin, Maine, showed that the total radiance of pixels contained in three snow courses varied from 5.34 to 7.74 mW/sq cm sr for a water equivalent of approximately 24.1 cm (9.5 in.) of water. This correlation ween radiance values and water equivalent of the anowpack needs to be tested. A multispectral signature was cloped with an accuracy of 75% for a wetlands category he Merrimack River estuary. Low-water reservoir and developed with an accuracy of 75% for a wetlands category in the Merrimack River estuary. Low-water reservoir and flood water stages were mapped from grayscale printouts of MSS band 7 for October 27, 1972, and July 6, 1973, respectively, for the Franklin Falls reservoir area, New Hampshire. Two snow pillow transducer systems for measuring the water equivalent of the snowpack in northern Maine were interfaced and field tested. A water quality monitor interfaced to the Landsat DCS was field tested in northern Maine and transmitted the following water quality information: pH, dissolved oxygen, river stage, water temperature and conductivity. A thermocouple system was successfully interfaced and field tested at Sugarlosf Mountain, Maine. Temperature data from the surface to a depth of 30 m (100 ft) were transmitted through the Landsat DCS. Also, a tensioneter/transducer system to measure moisture tension and soil volumetric moisture content was successfully interfaced to the Landsat DCS.

FRESH WATER SUPPLY FOR A VILLAGE SUR-ROUNDED BY SALT WATER—POINT HOPE,

McFadden, T., et al, Apr. 1978, 18p., ADA-054 147, 9 refs.

32-3964 WATER SUPPLY, GROUND WATER, PERMA-FROST HYDROLOGY.

FROST HYDROLOGY.

Point Hope is a village located on a narrow gravel spit textending eight miles out into the Bering Sea. Studies to locate an adequate fresh water source for the village have yielded two possible supplies which will fill the needs of the village. The first is a ground water supply existing on top of the undulating permafrost layer which underlies the gravel spit. This supply consists of several million gallons of water and can be augmented with snow fences which will drift blowing snow into areas where it will drain into the aquifer when it melts. Excess water will overflow the sides of the natural permafrost basin into the ocean on both sides of the spit. The second source is a small lake located approximately four miles from the village. The lake provides water of adequate quality and quantity to be used as a raw water supply; however, this source is not as desirable since it is surface water and supports a higher level of bacterial contamination. In addition, it is a much greater distance from the village, and longer, higher level of bacterial contamination. In addition, it is a much greater distance from the village, and longer, much more expensive piping would be required to get the water to the village.

SR 78-08 METHODOLOGY FOR NITROGEN ISOTOPE ANALYSIS AT CRREL

Quarry, S.T. 32-4374

SOIL CHEMISTRY, WASTE DISPOSAL, ISO-TOPE ANALYSIS, NITROGEN ISOTOPES, COM-PUTER APPLICATIONS.

PUTER APPLICATIONS.

This report documents the chronology of events and the procedures employed in developing a nitrogen isotope analysis capability at the U.S. Army Cold Regions Research and Engineering Laboratory. Both the instrumental and wet chemistry procedures are reported to enable others interested in the procedures to obtain useful data. The procedures described have resulted in the ability to measure the 15-N/14-N ratio to a precision of 0.001 atom %, a value easily within the acceptable range for tracer experiments. SR 78-09

IMPROVED DRAINAGE AND FROST ACTION CRITERIA FOR NEW JERSEY PAVEMENT DE-SIGN. PHASE 2: FROST ACTION. Berg, R.L., et al, May 1978, 80p., ADA-055 785, Nu-

merous refs. passim.

McGaw, R. 32-4380

FROST ACTION, PAVEMENTS, FROST HEAVE, DRAINAGE, THERMAL CONDUCTIVITY, FROST PENETRATION, SOIL FREEZING, COM-PUTER APPLICATIONS.

Before constructing actual pavements with open-graded drainage layers in New Jersey, the influence of the drainage

layer on frost penetration beneath hypothetical pavements was analytically examined. Thermal conductivity values of several New Jersey soils, stabilized drainage layer materials, and pavement samples were measured using the Guarded Hot Plate method or the probe method. Frost penetration depths were computed using the modified Berggren equations. Mean air freezing indexes used in the computation ranged from 50 deg-days in Atlantic City to 480 deg-days in Newton. Design freezing indexes ranged from 250 deg-days to 900 deg-days for the same two sites. Maximum computed frost depths ranged from 0.8 to 2.1 ft beneath conventional paverments, i.e., those without drainage layers. For pavements incorporating an open-graded drainage layer, computed maximum frost depths ranged from 0.8 ft to 1.4 ft. It was concluded that frost penetration beneath a pavement including an open-graded drainage layer would be approximately equal to a pavement without the drainage layer at the same site.

1977 TUNDRA FIRE AT KOKOLIK RIVER. ALASKA.

Hall, D.K., et al, Aug. 1978, 11p., ADA-062 439, 10 refs. For this paper from another source see MP 1125, 32-4577.

BORNE PHOTOGRAPHY, LANDSAT.

During summer 1977 widespread fires occurred in northwest Alaska. Through the use of Landsat imagery and ground studies, one such fire, at Kokolik River was examined. The Kokolik fire was first reported on 26 July, and by the time it was extinguished had consumed 44 sq km of tundra vegetation. Streams and drainages contained the fire on several sides. Ground observations provided information on the intensity of the fire effects. Depth of thaw by late August measured 35.4 cm in the burned areas and 26.6 cm in the unburned areas.

CONSTRUCTION EQUIPMENT PROBLEMS AND PROCEDURES: ALASKA PIPELINE PRO-JECT.

Hanamoto, B., June 1978, 14p., ADB-029 226, 4 refs. Distribution limited to U.S. Government agencies

only. 33-1535

COLD WEATHER PERFORMANCE, CONSTRUCTION EQUIPMENT, PIPELINES, ENGINES, HUMAN FACTORS.

The Trans-Alaska pipeline construction project posed many problems which are not encountered in the more temperate regions. Construction equipment maintenance and opera-tion is of major concern in the far north. Difficulties encountered were due to: extreme low temperature of -30F (-57C) and common winter temperatures of -30F (-34C), the remoteness and isolation of the work area, harsh environment, and the working personnel. This report de-scribes some of the typical problems encountered with con-struction equipment on this project and some of the remedies and procedures for solving these problems.

SR 78-12 SOIL LYSIMETERS FOR VALIDATING MODELS OF WASTEWATER RENOVATION BY LAND APPLICATION.

Iskandar, I.K., et al, June 1978, 11p., ADA-059 994, 12 refs.

33-1536 MOISTURE METERS, WATER TREATMENT, WASTE DISPOSAL, MODELS.

This report describes the construction, operation and performance of large-scale (90 cm-inside diameter and 150-cm-high) lysimeters. These lysimeters can continuously monitor soil moisture flow, soil temperature and redox potential with depth, and sample soil water and soil air with depth. The depth, and sample soil water and soil air with depth. The rate of soil water movement to the groundwater was continuously monitored by a rain gage and a recorder. To simulate field condition, an automatic spray system was developed; this system is also described in this report. The total cost of one lyaimeter is approximately \$650 (1975 estimate). The total cost of one lyaimeter is approximately \$650 (1975 estimate). The lysimeters are being used to validate a biophysical-chemical model of wastewater renovation by application to land. Detailed blueprints of the lyaimeters are kept at CRREL and are available on request.

ECOLOGICAL BASELINE INVESTIGATIONS ALONG THE YUKON RIVER-PRUDHOE BAY HAUL ROAD, ALASKA.

Brown, J., ed, Sep. 1978, 131p., ADA-060 255, For this item as a progress report to the U.S. Department of Energy and for individual papers see 32-3888 through 32-3896.
33-1537

33-1537
RESEARCH PROJECTS, ECOLOGY, TUNDRA VEGETATION, ROADS, CLAY SOILS.
Results of the first full year's field research on five projects along the Yukon River-Prudhoe Bay Haul Road are reported. Several projects are extensions of investigations begun in 1976 and are being conducted in cooperation with a Federal

Highway Administration sponsored environmental engineering study. The extent and success of weeds and weedy species along the road and in material sites has been followed for summer 1976 and 1977. In order to document the vegetation along the complex elevational and latitudinal gradient and its potential for impact and recovery, 17 vegetation maps have now been completed, and vegetation described and plots established at 120 locations along the 600-kilometeriong road. Collections of vascular plants, bryophytes and lichens were made and catalogued for an additional 9 sites. Sampling for soil invertebrates to determine their sensitivity to impact was undertaken at approximately 25 sites. A detailed study of the impact of road dust upon the vegetation was initiated at one tundra site, and four sites were established to monitor the amount of dust transported onto the tundra across 1000-meter-long transects. The clay mineralogy and chemistry of the dust and road material were investigated. SR 78-14 Highway Administration sponsored environmental engineering

GROCHEMISTRY OF SUBSEA PERMAFROST AT PRUDHOE BAY, ALASKA. Page, F.W., et al, Sep. 1978, 70p., ADA-060 434, Refs. p.62-68. Iskander, I.K.

33-1543

SUBSEA PERMAFROST, SEDIMENTS, SEA WATER, CHEMICAL ANALYSIS, DRILL CORE ANALYSIS, SALINITY.

ANALYSIS, SALINITY.

The analytical data from sediment, interstitial water, and seawater analyses of samples collected near Prudhoe Bay, Alaska, during the period from March to May 1977, are presented. Analyses include determinations of moisture, calcium carbonate, and organic carbon contents in the sediment samples and pH, electrical conductivity, alkalinity, and concentrations of sodium, potassium, calcium, magnesium, chloride, and sulfate in the interstitial water and seawater samples. Salinity, ionic balance, and freezing point of the water samples were calculated. The marine sediments in Prudhoe Bay generally contain more calcium carbonate, organic carbon, and interstitial water than the underlying glacial and fluvial gravels. On land, a surficial layer of peat also had high organic carbon and moisture contents. The salinity of the seawater samples varied from concentrated brines near the shore where sea ice is frozen directly to, or is located near, the sea bottom to water which was 1.0 to 1.5 ppt less saline than normal seawater at a distance of approximately 10 to 15 km from shore.

WASTES, WATER CHEMISTRY, ISOTOPIC LA-BELING, RESEARCH PROJECTS.

BELING, REBEARCH PROJECTS.

The fate of the mineral nitrogen in wastewater can be established only through natural or artificial stable isotopic labeling. This report assesses the possibilities and problems associated with such tracer techniques applied to the small amounts of nitrogen normally present after secondary waste treatment. The methods outlined for sample processing to minimize analytical errors are applicable to other types of environmental research involving isotope ratio analysis as a means of tracing nitrogen in the biosphere.

SR 78-19 SELECTED BIBLIOGRAPHY OF DISTURBANCE AND RESTORATION OF SOILS AND VEGETATION IN PERMAPROST REGIONS OF THE USSR (1970-1977).

Andrews, M., Oct. 1978, 175p., ADA-062 339.

BIBLIOGRAPHIES, HUMAN FACTORS, ENVI-RONMENTAL IMPACT, CONTINUOUS PER-MAFROST, DISCONTINUOUS PERMAFROST, REVEGETATION, CRYOGENIC SOILS, DAM-AGE.

AGE.

This compilation of literature, published in Russian since 1970, comprises 1225 bibliographic citations relating to disturbance and restoration of soils and vegetation. Sixty-five percent of these were found by a manual search of CREEL bibliography Vols. 25-32; the others were obtained through off-line searches from the relevant computerized data bases and personal files. Only one of these data bases, that of the National Agricultural Library, is shown to be of significance in providing a valuable checking source. The literature is discussed in chronological fashion, with general statements followed by highlights of each year's contributions. The years 1972 and 1973 produced the most publications by the indexing services. A trend is apparent from a reconnaissance and description approach in earlier papers toward an integrated ecosystem approach in earlier papers toward an integrated ecosystem approach in more recent toward an integrated ecosystem approach in the effects of disturbance on the permafrost environment, and the importance of restoration and preservation of these environments, are reflected in the recent literature, particularly in symposium proceedings.

SR 78.20 EFFECTS OF WASTEWATER AND SEWAGE SLUDGE ON THE GROWTH AND CHEMICAL COMPOSITION OF TUREGRASS.

Palazzo, A.J., Nov. 1978, 11p., ADA-061 878, 17 refs. 33-1349

WASTE DISPOSAL, SEWAGE DISPOSAL, GRASSES, GROWTH, CHEMICAL COMPOSI-TION.

TION.

A greenhouse study was conducted to determine the effects of wastewater and sewage applications on the growth and chemical composition of two turfgrass mixtures. A mixture of tall fescue and annual ryegrass. As mixtures of Kentucky bluegrass, red fescue and annual ryegrass. The mixtures were grown in pots of Charlton silt loam in a greenhouse. Prior to seeding, soil in some pots was amended with sludge at rates of 45 or 90 g/pot. Commercial fertilizer supplying N, P, and K was incorporated with soil in pots designated as controls. Treated municipal wastewater was applied on unamended and sludge-amended soil at rates of 5 or 10 cm per week. Wastewater and sludge treatment increased yields, and total uptake of N, P, K, Za, Cd, P, Cu, and Ni by the turfgrasses differed by treatment. The two grass mixtures were similar with regard to yields and composition. Larger yields corresponded to greater plant uptake of N, P, K, and metals. SR 78-21

CLIMATIC SURVEY AT CRREL IN ASSOCIA-TION WITH THE LAND TREATMENT PRO-JECT.

Bilello, M.A., et al, Nov. 1978, 37p., ADA-062 518, 39 refs.

33-1542

MICROCLIMATOLOGY, WASTE DISPOSAL, WATER TREATMENT, WASTE TREATMENT, METEOROLOGICAL DATA.

METEOROLOGICAL DATA.

During 1972, six test cells were constructed at CRRBL for the purpose of studying application of wastewater on various soil types and vegetation. In conjunction with this program, a meteorological observing station was established in order to obtain basic information on the climate proximate to the test cells. This report describes the equipment and its installation, and provides a daily tabulation of the following observed parameters: maximum and minimum air temperatures, relative humidity, dew point, wind speed and direction, precipitation amounts, depth of snow on the ground, solar radiation and pan evaporation. The meteorological data collected during the period starting Oct. 1, 1972, to Mar. 31, 1974, were then summarized; and the results are presented in a series of graphs and line diagrams. The meteorological parameters recorded at CRRBL were then examined to determine how weather can constrain or

help year-round operation of wastewater application to the land. The positive and negative effects of air temperature, precipitation, wind speed, evaporation and snow cover, with respect to land treatment of wastewater, were evaluated. Although no specific recommendations or conclusions are given, the influences of these climatic elements as observed at the CRREL wastewater site are presented for consideration.

COMPUTER FILE FOR EXISTING LAND AP-PLICATION OF WASTEWATER SYSTEMS: A USER'S GUIDE.

Iskandar, I.K., et al, Nov. 1978, 24p., ADA-062 658, 4 refs.

Robinson, D., Willcockson, W., Keefauver, E. 33-2521

WASTE DISPOSAL, WATER TREATMENT, COMPUTER PROGRAMS.

COMPUTER PROGRAMS.

Two computer programs, both written in BASIC, have been developed to store and retrieve information on existing wastewater land treatment systems. The purpose of establishing these programs is to provide assistance to design engineers during the planning of new land treatment systems by making available the design criteria and performance characteristics of operating systems. The SEARCH program is designed to locate systems with specific design parameters, such as flow rate, waste type, capilication rate and mode, ground cover and length of operation. The printout from SEARCH includes a list of articles on similar systems in addition to the design parameters. The UPDATE program is used for the revision of information on file. Currently, there are about 350 domestic and 75 foreign systems on file.

SR 78-23 ENGINEERING ASPECTS OF AN EXPERIMEN-TAL SYSTEM FOR LAND RENOVATION OF SECONDARY EFFLUENT.

WASTE DISPOSAL, WATER TREATMENT, WASTE TREATMENT, IRRIGATION, LAND RECLAMATION.

RECLAMATION.

A research system was designed and installed at the Apple Valley Wastewater Treatment Plant, two miles south of Rosemount, Minnesota, to develop agricultural management practices for removal of nitrogen from municipal wastewater effluent. A solid set irrigation system was designed and installed to apply wastewater effluent to 1.2 test blocks, each measuring 60 x 150 ft. A perforated plastic drainage tile was placed lengthwise in each block at a depth equivalent to the normal water table level and opening at one end of the block into a sampling station. Six blocks were planted to corn and six planted to eight species of forages. The effluent was applied at rates up to 15 ft/yr. This report presents the engineering considerations in the design of a solid set irrigation system and drain tile and monitoring system for evaluating the influence of the effluent application and agronomic practices on drainage waters. and agronomic practices on drainage waters.

ROOF CONSTRUCTION UNDER WINTER-TIME CONDITIONS: A CASE STUDY. Bennett, F.L., Nov. 1978, 34p., ADA-062 519.

ROOFS, COLD WEATHER CONSTRUCTION, INSULATION, CONSTRUCTION MATERIALS. This report describes construction of the roof of an addition to the Interior City Branch of the First National Bank of Anchorage, located in downtown Fairbanks, Alaska, during the 1976-77 winter. The report documents the schedule and procedure for building the roof, reports successful performance of the roof to date, and presents some general comments on roof construction in the wintertime.

INCREASING THE EFFECTIVENESS OF SOIL COMPACTION AT BELOW-PREEZING TEM-PERATURES Haas, W.M., et al, Nov. 1978, 58p., ADA-062 875, 57

Alkire, B.D., Kaderabek, T.J.

SOIL COMPACTION, FROZEN GROUND COM-PRESSION, COMPRESSIVE STRENGTH, SOIL WATER, CHEMICAL REACTIONS.

This report presents data from an experimental program undertaken to determine the effect of low temperatures on the compaction characteristics of a sitty sand. The effects of compactive effort and chemical additives were also investigations. of compactive effort and chemical additives were also investigated to determine possible methods of improving the densities of soils placed and compacted at low temperatures. A single soil type was used throughout the test program, and test results were obtained using Standard and Modified AASHO compactive efforts on an untreated soil prepared and tested at temperatures of 20C and -7C. Additional test series, using the same compactive efforts and temperatures, were performed on the soil after it had been treated with an additive. The amounts of additive used, based on the dry weight of soil, were 3, 2, 1, 0.5, and 0.25% of calcium chloride and 0.5% of sodium chloride. From the results of the experimental program, several important conclusions concerning the effect of low temperature compaction were drawn. SR 78-26

Korhonen, C. 33-2525

ROOFS, MOISTURE TRANSFER, DETECTION, INFRARED SPECTROSCOPY.

INFRARED SPECTROSCOPY.

Nuclear, infrared, capacitance, microwave and impulse radar methods for nondestructively detecting moisture in roots were evaluated. No system was reliable enough by itself or by cross-checking with another system to eliminate the need for a few core samples of membrane and insulation to verify findings. Airborne infrared surveys are a cost-effective way of reconnoistering numerous roofs at a major installation. However, follow-up on-the-roof surveys are necessary. Of the several prid techniques examined, nuclear surveys were the most reliable. Hand-held infrared surveys are the most accurate on-the-roof method studied. Although infrared camera costs significantly more than a nuclear meter (\$27,000 vs \$3,000), infrared surveys can be conducted more rapidly. Where numerous roofs are to be surveyed, infrared surveys appear to be the most cost-effective method. In-situ measurements have been made of the thermal resistance of wet and dry portions of roofs. A laboratory apparatus has been built to subject 12 in x 12 in specimens of roof insulation to combined thermal and moisture gradients. Thermal resistance and moisture content are periodically determined, and characteristic curves are being developed for various roof insulations.

RONMENTS.

Patterns of communication and social interaction within a work organization are significantly influenced by architecture. Nearly all work organizations are dependent upon information flow, both informal and formal, between coworkers. As a rule, the more open and informal the communication, the more productively and efficiently the organization operates. The architectural design concept of focal points is presented as a strategy for planning the work facility for improved informal communication. Examples of energy-efficient building design schemes for cold regions are presented. These prototype buildings combine design for improved worker efficiency with thermal efficiency.

PRELIMINARY INVESTIGATIONS OF THE KINETICS OF NITROGEN TRANSFORMATION AND NITROSAMINE FORMATION IN LAND TREATMENT OF WASTEWATER.

WASTE DISPOSAL, WATER TREATMENT, SOIL CHEMISTRY, LABORATORY TECHNIQUES.

CHBMISTRY, LABORATORY TECHNIQUES.
In laboratory experiments, denitrification of nitrate in wastewater proceeded slowly in an acid soil (pH 4.2), but the rate was fast in soils with pH values of 5.5 to 6.8. The rate of denitrification was governed by the carbon source added, with glucose supporting the fastest rate. The rate was somewhat slower with methanol and succinate and was appreciably slower with secondary effluents as the source of supplemental carbon. Charlton loam supported the more

rapid denitrification with glucose as a carbon source, but the rate was higher in Windsor sandy loam with sewage as the carbon source. Denitrification in these soils did not occur at IC, and the rate increased with rising temperatures.

SR 79-05 PHYSICAL AND THERMAL DISTURBANCE AND PROTECTION OF PERMAPROST, Brown, J., et al, Mar. 1979, 42p., ADA-069 405, Nu-

Grave, N.A.

33-3830

PERMAPROST PRESERVATION, THERMAL STRESSES, HUMAN FACTORS, PERMAPROST DISTRIBUTION, DAMAGE.

DISTRIBUTION, DAMAGE.

This report is based on a review paper presented at the Third International Conference on Permafrost held in July 1978 at Edmonton, Canada. It reviews the literature covering 1974-1978 and covers subjects related to natural and human induced disturbance of terrain underlain by pprmafrost. Subjects include investigations undertaken in conjunction with oil and gas pipelines, terrain mapping, methods for estimating terrain sensitivity, methods of protecting terrain, and the thermal effects of off road transportation, oil spills, fire, removal of the surface soil layers, anow conditions, mining and other construction practices. Methods of protecting and restoring permafrost in the USSR are presented in tabular form. An appendix summarizes results of modeling and microclimatic investigation, and the distribution and properties of subsea, land-based, and alpine permafrost.

SPRAY APPLICATION OF WASTEWATER EF-FLUENT IN WEST DOVER, VERMONT: AN INI-TIAL ASSESSMENT.

Cassell, E.A., et al, Apr. 1979, 38p., ADA-068 534, 26

WASTE DISPOSAL, WATER TREATMENT, SOIL CHEMISTRY, WATER CHEMISTRY.

Runoff from spray application of secondary wasten a forested hillside in West Dover, Vermont, Runoff from spray application of secondary wastewater effluent on a forested hilliside in West Dover, Vermont, was monitored for a six-week period (11 July-19 August 1977). Both quantity and quality of applied effluent and site drainage were monitored. On-site groundwater and two adjacent streams were sampled for water quality. Drainage flows were relatively constant during the study period in spite of highly variable inputs to the site. There is evidence that substantial quantities of water may be leaving the spray site by moving through the subsurface fraginen layer. On a mass basis, 95% of the total nitrogen, 96% of the ammonia nitrogen, 92% of the total phosphorus, and 79% of the ODDS were removed by spray application. Heavy precipitation was observed to flush most nutrient forms, especially nitrate-nitrogen, from the spray site. Groundwater on the spray field contained lower concentrations of nutrient than did the applied effluent, but higher concentrations than those found in site drainage.

No leavandors of nutrient were detected during the study period. However, there was some evidence of increased chloride concentrations in Ellis Brook.

SR 79-07 ENERGY REQUIREMENTS FOR SMALL FLOW VASTEWATER TREATMENT SYSTEMS Middlebrooks, B.J., et al, Apr. 1979, 82p., ADA-070 676, 16 refs. Middlebrooks, C.H.

PONDS, SEEPAGE, SEEPAGE, COST ANAL-

This report summarizes energy requirements for small wastewater treatment systems (0.05 - 5 million gallons per day) applicable to military installations. It compares various treatment combinations and manufacture of the compares of the compares of the compares various treatment combinations. applicable to military installations. It compares various treatment combinations, and presents the energy requirements for the most viable alternatives in tabular form. It also presents energy requirements for various components of waterwater treatment systems in a format making it convenient to calculate the energy requirements for many combinations of the components. In addition, it summarizes briefly energy estimates made by others. The report compares typical combinations of unit operations and processes used to produce various quality effluents on the basis of energy consumption. It concludes that land application systems are the most energy-efficient wastewater treatment systems and that they are capable of producing an equivalent or higher quality effluent than any other treatment system.

SR 79-08 **DESIGN PROCEDURES FOR UNDERGROUND**

HEAT SINK SYSTEMS.
Stubstad, J.M., et al, Apr. 1979, 186p. in var. pagna., ADA-068 926, 65 refs.
Quinn, W.F., Greenberg, M., Beat, W.C., Botros,

33-3427 UNDERGROUND FACILITIES, HEAT TRANS-FER, WASTE DISPOSAL, HEAT RECOVERY, HEAT SINKS.

This report presents criteria, engineering information and estimation procedures for the disposal of waste heat associated with the generation of power required to supply the needs of hardened defense underground installations. The major emphasis is placed on the temporary disposal of waste heat below ground while the installation is under attack and cannot rely upon aboveground disposal. A series of sample problems is included to illustrate the use of the estimation procedures presented in the report. All of the sample problems are based on the sizing of a heat sink system for an underground nuclear power plant. Under the design criteria which were assumed for the sample problems, it is shown that the combination ice/water type heat sink concepts provide the most cost effective solutions.

SR 79-09 ESTIMATED SNOW, ICE, AND RAIN LOAD PRIOR TO THE COLLAPSE OF THE HART-FORD CIVIC CENTER ARENA ROOF. Redfield, R., et al, Apr. 1979, 32p., ADA-069 323, 19

son, W., Colbeck, S.C. 33-4673

ROOPS, LOADS (FORCES), SNOW LOADS, ICE LOADS, RAIN.

LOADS, RAIN.

The roof of the Hartford, Connecticut, Civic Center Arena collapsed under an unknown load of snow, ice and rain early in the morning on Isn. 18, 1978. Based on available meteorological and snow load measurements, estimates for the amount of load present at the time of failure are made using a number of techniques. In addition, previous maximum loads due to snow, ice or rain since the building was constructed are also estimated.

RAPID DETECTION OF WATER SOURCES IN COLD REGIONS—A SELECTED BIBLIOGRA-PHY OF POTENTIAL TECHNIQUES.

Smith, D.W., comp, May 1979, 75p., ADA-070 030. Smith, G.A., comp, Brown, J.M., comp, Schraeder, R.L., comp, Kosikowski, L., comp.

BIBLIOGRAPHIES, GROUND WATER, WATER SUPPLY, DETECTION, ELECTRICAL RESIS-

A review of current literature on existing techniques that could be utilized in the rapid location of water sources for field camp use in permafrost regions resulted in the selection of three non-ground contact methods of electrical resistivity and two radar methods as being the most effective techniques.

The search included thousands of references; 77 of these were chosen to be included in the annotated bibliography. The interest level or pertinence of each entry to the study is indicated, and keywords are provided. The keyword index contains all keywords for all entries listed in alphabetical order.

SEEKING LOW ICE ADHESION.
Sayward, J.M., Apr. 1979, 83p., ADA-071 040, 54 33-4226

33-4226 ICE ADHESION, ADHESIVE STRENGTH, ICE PREVENTION, ICE SOLID INTERFACE, WETTABILITY, COHESION, POLYMERS, ICE REMOVAL, SURFACE PROPERTIES, SURFACE ENERGY.

MOVAL, SURFACE PROPERTIES, SURFACE ENERGY.

Icing impairs operation of helicopters and other aircraft, antennae, power and communication lines, shipping and superstructures, canal locks, etc. Prevention or easier removal of icing requires reduction of its adhesion strength. Literature study shows that adhesion results from secondary (van der Wasis) forces yet exceeds normal cohesive strengths. It depends on free surface energy, low contact angle, good contact and wetting, cleanliness, and texture. Modes of adhesion testing are briefly discussed. Poor adhesion occurs with low energy surfaces or contaminants, e.g. hydrocarbons, fluorocarbona, waxes, oils, etc., particularly when textured or porous. The resulting low contact angle, poor wetting and occlusion of air at the interface weaken the bond or provide stress loci which can initiate cracks and failure. Coefficient of expansion differences may help in release of ice. Further ideas appear among the 100 abstracts presented. A survey of over 300 manufacturers produced over 100 replies. Half of them offered some 100 products deemed worth testing. These are listed with addresses and contacts. Besides simple resins and other release agents, they include composities which combine low surface energy and stronger materials as micro-mixture, interpeneerating-network, "plastic-alloy," or filler-matrix systems. About 15 to 20 products appear of special interest. Samples of liquid coating or supplier-prepared panels of many are available for the testing phase to follow.

SR 79-12

FREEZING PROBLEMS ASSOCIATED WITH SPRAY IRRIGATION OF WASTEWATER DUR-ING THE WINTER.

Bouzoun, J.R., May 1979, 12p., ADA-070 031, 5 refs. 34-136

WASTE TREATMENT, WATER TREATMENT, WASTE DISPOSAL, IRRIGATION, ICE PREVEN-TION.

During the winters of 1975-76, 1976-77 and 1977-78, biologically treated wastewater was applied to land in West Dover,

Vermont. The wastewater was applied using the spray irrigation method at ambient temperatures as low as 0F. During the first winter, freezing was a major problem. Modified spray nozzles that were less susceptible to freezing were installed at both the low points and high points of the aboveground spray laterals. During the second and third winters, ice buildup along the spray laterals, particularly in the vicinity of the spray nozzles, caused serious damage to the rives. Many membeurs were required to cut the in the vicinity of the spray nozzles, caused serious damage to the pipes. Many man-hours were required to cut the ice repeatedly from the laterals. As an experiment to alleviste the problem, several 30- to 36-in risers were installed at an angle of approximately 30 degrees from the vertical on two of the spray laterals during the winter of 1977-78. They functioned well enough to warrant future installation on the entire system of spray laterals.

SR 79-13 PHOTOELASTIC INSTRUMENTATION— PRINCIPLES AND TECHNIQUES. Roberts, A., et al, May 1979, 153p., ADA-072 011, 83

Hawkes, I.

MEASURING INSTRUMENTS, OPTICAL PROP-ERTIES, STRESSES, ELASTIC PROPERTIES, IN-DICATING INSTRUMENTS, PHOTOELASTICI-

TY.

This report contains a detailed review of the theory and design of photoelastic transducers for measuring loads, strains, stresses and pressures. The measurement of engineering parameters under the adverse conditions normally encountered in the mining and civil engineering industries presents great problems, particularly where such measurements are to be made over long periods of time. Photoelastic transducers have distinct advantages over competing equipment in this respect in that the parameters to be measured are revealed as light interference fringes, and the measuring gage itself often need consist of nothing more than simple steel and glass components. Examples of such gages are given in the report. The majority of the work reported here was carried out by the staff and students of the Postgraduate School of Mining, Sheffield University.

ELECTROMAGNETIC GEOPHYSICAL SURVEY AT AN INTERIOR ALASKA PERMAFROST EX-

Sellmann, P.V., et al, May 1979, 7p., ADA-071 065, 5 refa.

AL PREEZE THAW.

Road construction activity near Fairbanks, Alasks, in the late full of 1977, revealed a large exposure of Fairbanks silt containing numerous massive ice features. These exposures are typical of those found in this region. Thaw, during the summer of 1978, caused the upper loo-rich sections to retreat several metera. Goophysical techniques were utilized over these exposures to determine if resistive anomalies of ice wedge dimension could be detected. Magnetic induction measurements at three intercoil spacings and low-frequency surface immediance measurements were made about induction measurements at times intercoil spacings and sow-frequency surface impedance measurements were made about 6 m from the edge of each exposure in April 1978 before thaw commenced. The results agree well with observations of the layering, but most individual anomalies are difficult to interpret because the lateral extent of the ice is unknown.

SR 79-15

IMPROVED DRAINAGE AND FROST ACTION CRITERIA FOR NEW JERSEY PAVEMENT DE-SIGN. PHASE 2 (DATA ANALYSIS). Berg, R.L., May 1979, 51p., ADA-071 041, 7 refs. 33-4228

FROST PENETRATION, SUBSURFACE DRAIN-AGE, MOISTURE, FREEZING INDEXES, PAVE-MENTS.

MENTS.

Before constructing actual highway pavements with open-graded drainage layers, frost penetration depths and moisture content profiles were measured beneath several pavements in New Jersey. Air and surface freezing indexes were measured at three locations during the 1975-1976 and 1976-1977 winters. All freezing indexes were considerably greater during the 1976-1977 winter. The modified Berggren equation was used to compute the maximum frost depth at 30 test sites. Measured maximum frost depths ranged from 20.5 in. to 52.0 in., while computed maximum values ranged from 14.0 in to 61.0 in. The mean difference between observed and computed maximum frost penetration depths was 3.8 in. Maximum frost penetration depths were computed for hypothetical pavements with open-graded drainage at four of the test sites. It was concluded that open-graded drainage layers would not significantly change the frost penetration beneath highway pavements in New Jersey. It was recommended that test pavements be installed to verify the computations. Jersey. It was recommendations.

ROOF MOISTURE SURVEY-U.S. MILITARY

ACADEMY. Korhonen, C., et al, May 1979, 8 refs. Tobiasson, W.

33-4229

ROOFS, WALLS, LEAKAGE, INSULATION, MOISTURE, INFRARED EQUIPMENT, MEASURING INSTRUMENTS.

SURING INSTRUMENTS.

The roofs and upper story walls of buildings 745E, 752, and 756 at the U.S. Military Academy, West Point, New York, were surveyed with a hand-held infrared camers to locate sources of reported wall leaks. An electrical resistance probe was used to determine the relative level of moisture in wall components. Several 3-in-dism core samples of each roof were obtained to verify suspected moisture conditions and to examine the roof membrane in cross section. Wet areas on each roof were outlined with white spray peint. Wall leaks are believed to becaused by wind-driven rain entering the parapet walls in locations where the decorative glazo-cost has spalled off. Recommendations for maintenance of these buildings are based on information derived from the infrared survey, electric resistance readings, core samples and visual examinations.

SMALL-SCALE TESTING OF SOILS FOR FROST ACTION AND WATER MIGRATION. Sayward, J.M., May 1979, 17 p., ADA-071 989, 25

33-4435
SOIL TESTS, FROST ACTION, SOIL WATER MIGRATION, FROST HEAVE, ICE NEEDLES.

GRATION, FROST HEAVE, ICE NEEDLES.

A method is described by which frost action (soil beaving and and needle ice) and the use of soil additives for its control can be studied. The apparatus and procedure are simple and convenient, requiring no extensive space or services and using only small quantities of materials. The procedure could be useful in developing a standard test for such purposes where small scale and convenience are requisite. Also described are two simple, small-scale accessory tests that likewise relate to permeability of soils. These evaporation and wetting tests might also have similar use, particularly in the study of water migration-inhibiting additives.

WASTE TREATMENT, WATER TREATMENT, SOIL MICROBIOLOGY, LAND RECLAMA-TION, ARCTIC REGIONS.

SOIL MICROBIOLOGY, LAND RECLAMATION, ARCTIC REGIONS.

A series of laboratory and field tests was conducted to investigate the possibility that nitrapyrin could be useful as a nitrification inhibitor in land treatment of wastewater. Laboratory tests included soil incubation and soil column studies. Variables were soil type, temperature, nitrapyrin concentration and method of application to the soil. Experimental designs included two soils, three temperatures (0, 10 and 20°C) and three levels of inhibitors in a complete factorial. Forage grasses were present in all treatments, and wastewater containing NH4+ was utilized. Weekly application of wastewater was 5 cm. Soil solution at depth and leachate at 160 cm were collected and analyzed weekly for NH4N and NO3N. That data indicate that nitrapyrin was not effective in inhibiting nitrification when applied to the soil surface in soil columns simulating land treatment slow infiltration. The ineffectiveness of the compound under a mode of application where it is mixed and sprayed with wastewater is thought to be due to its volatility, sorption by organic matter, low water solubility and its immobility in soils. Other chemicals such as carbon disulfide and thiocarbonates, which have different characteristics than the nitrapyrin, showed promising results. Research is under way to obtain conclusive data.

SR 79-19 DRAINAGE NETWORK ANALYSIS OF A SUBARCTIC WATERSHED: CARIBOU-POKER CREEKS RESEARCH WATERSHED, INTERIOR AT.ASKA.

Hoch. D.

WATERSHEDS. DRAINAGE, SLOPE PRO-CESSES, PERMAPROST.

CESSES, PERMAPROST.

A Strahler stream order analysis and an exterior link length distribution analysis were made of the Caribou-Poker Creeks Research Watershed near Pairbanks Alaska. The drainage network map used for analysis was produced using a 1:2250 scale aerial photograph measic. Low drainage densities characterize the basins. Bifurcation ratios indicate that the overall drainage network is not dominated by strong geologic controls. Statistical analysis indicates that bifurcating source links and tributary source links do not belong to the same length population, a characteristic abared by watersheds in other climatic regions of the world. Additional analysis indicates that exterior links originating on permafrost

slopes tend to be shorter than those originating on non-permafrost, well-drained slopes.

INFRARED THERMOGRAPHY OF BUILD-INGS: 1977 COAST GUARD SURVEY.

Marshall, S.J., June 1979, 40p., ADA-073 596, 9 refs. 34-138

BUILDINGS, HEAT LOSS, INFRARED PHO-TOGRAPHY, WINDOWS.

An IRTB (infrared thermography of buildings) field survey, producing 631 thermograms, 127 photographs, and weather data, was conducted during a 14-day study of 10 Coast Guard stations in Maine, New Hampshire and Massachusetts. This report discusses how the survey was initiated and per-formed with emphasis on details for the benefit of the reader formed with emphasis on details for the benefit of the reader wishing to plan a survey. One hundred twenty selected thermograms and photographs in this report illustrate many types of heat loss and compare thermally ineffective doors and windows with units designated as standards for thermal effectiveness. Radiator heat leakage through walls, mottled moisture patterns on brick walls, infiltration patterns on glass, and poorly covered openings are illustrated. Thermograms of severe heat loses through glass doors, glass transoms, and glass wall panels are also included, and several solutions for individual heat loss problems, such as fiberglass garage doors and porcelain insulated panels, are suggested. Unanticipated survey problems, such as difficulties in obtaining photographs to compare with thermographically discovered artifacts and adjustments to survey techniques for inclement weather, are also discussed.

DOCUMENTATION OF SOIL CHARACTERIS-TICS AND CLIMATOLOGY DURING FIVE YEARS OF WASTEWATER APPLICATION TO CRREL TEST CELLS.

Iskandar, I.K., et al, July 1979, 82p., ADA-074 712, 14

Quarry, S.T., Bates, R.E., Ingersoll, J.

WASTE DISPOSAL, WATER TREATMENT, SOIL CHEMISTRY, CLIMATOLOGY, METEORO-LOGICAL DATA.

LOGICAL DATA.

Section 1 deals with physical properties of the two soils used and the changes in soil chemical characteristics. The physical properties of the soil are those most important in controlling the rate of water movement in soils, such as saturated and unsaturated soil hydraulic conductivity, particle size distribution, bulk density, void ratio, available water and specific gravity. The chemical characteristics of the soil that are of potential importance in assessing the short and long-term effects of wastewater application on land include: free iron oxidea, organic carbon, organic nitrogen, pH, conductivity, cation exchange capacity, exchangeable cations, total and extractable phosphorus, and total and extractable heavy metals. Section 2 summarizes climatic conditions at the CRREL site in Hanover, New Hampshire, and the changes that occurred during the period 1974 to 1978. Climatic parameters include temperature, precipitation, wind speed, and soil temperature at depth.

DETERMINATION OF DISSOLVED NITRO-GEN AND OXYGEN IN WATER BY HEADS-PACE GAS CHROMATOGRAPHY. Leggett, D.C., July 1979, 5p., ADA-074 411, 25 refs. 34-744

LAKE WATER, WATER CHEMISTRY. In this study dissolved oxygen and nitrogen were determined by shaking 20 to 25 ml of water with an equal amount of helium in a 50-ml gas-tight syrings and injecting 2 ml of the equilibrated headgas into a gas chromatograph. Oxygen and nitrogen were separated on a 5-A molecular sieve column at ambient temperature and detected with a hot wire detector, using atmospheric air for calibration. Advantages of this method over previously reported methods are 1) oxygen and nitrogen are determined in a single analysis, 2) no specifically fabricated stripping apparatus is needed, and 3) analysis can be done in the field with completely portable, battery-operated equipment. The method appears to be accurate and reproducible; several lake O2 and N2 profiles were obtained using this technique.

SR 79-25 BULLET PENETRATION IN SNOW.

Cole, D.M., et al, July 1979, 23p., ADA-074 412, 14

Farrell, D.R.

SNOW (CONSTRUCTION MATERIAL), PRO-JECTILE PENETRATION, PENETRATION TESTS.

TESTS.

Three types of ammunition, the M193, M80, and M43, were tested. Rounds were fired into snow targets of various thicknesses up to that thickness required to fully stop the projectiles. The maximum penetrations for the three rounds tested were 0.70 m, 1.26 m and 1.06 m, respectively. Velocity loss as a function of target thickness was determined by measuring projectile velocity before and after impact of the projectile with the target. The velocity loss vs. thickness data showed a sigmoid shape common to the three types of rounds. The impact and exit yaw angles of the M193 rounds were estimated. Scatter in the test data was attributed, in part, to random variations in the impact yaw angle. The penetration required for a 90 deg yaw was determined by the exit yaw measurements. This was shown to correspond to the inflection point on the velocity loss vs. penetration curve. This point is potentially significant in the design of composite fortifications. Discussions deal with basic concepts and definitions, the occurrence and significance of projectile tumbling and the use of laboratory tests for small arms evaluation in snow targets. The validity of the methodology used was established by testing M193 rounds in galatin targets. These results compared favorably with similar test results in literature. SR 79-26

APPLICATION OF HEAT PIPES ON THE TRANS-ALASKA PIPELINE. Heuer, C.E., July 1979, 27p., ADA-073 597, 26 refs.

PIPELINES, HEAT PIPES, HEAT TRANSFER PIPELINES, HEAT PIPES, HEAT TRANSFER.

The application of heat pipes on the Trans-Alaska Pipeline is reviewed. The subjects addressed include the general functioning of a heat pipe, the specific heat pipe design used, the different situations where heat pipes were employed, the methods used to develop the heat pipe design, the methods used to monitor the operating heat pipes, and the performance of the heat pipes. The discussion is qualitative in nature. Quantitative information is largely omitted to allow coverage of a broad area and because it may be considered proprietary. Nevertheless, the information presented here should give a good appreciation of the quality and complexity of the heat pipe design. The information should also be useful in developing heat pipes for use in other cold regions applications. other cold regions applications

SR 79-27 EXTENDING THE USEFUL LIFE OF DYE-2 TO 1986, PART 1: PRELIMINARY FINDINGS AND RECOMMENDATIONS.

Tobiasson, W., et al, July 1979, 15p., ADA-074 733, 3 refs.

Korhonen, C., Redfield, R.

34-745 COLD WEATHER COLD WEATHER CONSTRUCTION, SHEETS, STEEL STRUCTURES, STRESSES. SHEBTS, STEBL STRUCTURES, STRESSES.

DEW Line Ice Cap Station DYE-2 appears to need major work within the next few years to extend its useful life to 1986. In structural steel frame is overstressed in a few areas, and the lower portion of the subsurface timber truss enclosure is in bad condition. Additional performance measurements are needed during 1979 to determine the rate of secondary stress in the structural steel frame and the rate of deterioration of the truss enclosure. With this information, a decision can be made whether to move the building stidways onto a new undistorted foundation to stabilize it in-place by encapsulating the lower 52 ft of the substructure in ice.

SR 79-28 UTILIZATION OF SEWAGE SLUDGE FOR TER-RAIN STABILIZATION IN COLD REGIONS.

Gaskin, D.A., et al, Aug. 1979, 36p., ADA-074 725, 10 refs. For Part 1 see 32-1368.
Palazzo, A.J., Rindge, S.D., Bates, R.E., Stanley, L.E.

34-746 SLUDGES, SEWAGE DISPOSAL, SOIL STABILI-ZATION, VEGETATION.

ZATION, VEGETATION, Prom June 1975 to Sep. 1976, a research/demonstration study was conducted at CRREL in Hanover, New Hampshire, to investigate the use of sewage sludge, commercial fertilizer and cultivation techniques for terrain stabilization in cold regions. Twenty-seven test plots on a 16-deg west-facing slope received various combinations of: 1) surface preparation (tilling, bulldozer tracking, or compacting), 2) nutrient source (sewage sludge or fertilizer), 3) mulching agent (wood fiber

mulch or peat moss), and 4) tacking agent (Terra Tack III or Curssol). The plots were seeded in either the spring or fall with a constant seed mixture. The effectiveness of the treatments was determined through vegetation yields and soil loss measurements.

WATER TREATMENT, WASTE DISPOSAL, IRRIGATION, AEROSOLS, MICROBIOLOGY.

RIGATION, AEROSOLS, MICROBIOLOGY.

An evaluation of microbiological aerosols resulting from the spray irrigation of wastewater under known atmospheric stability conditions was performed during July and August 1978 at the Deer Creek Lake land treatment system in Ohio. In the experiment, ponded chlorinated wastewater was sprayed onto a 6-acre test area with 96 impact sprinklers representing a multi-source field aerosol distribution system. Approximately 99.9% of the wastewater applied to the 23-hectare test area fell within the area of influence of the sprinkler (about a 20-m diam circle around the sprinkler riser) with only 0.10% of the applied wastewater aerosolized. Indigenous total aerobic bacteria in the wastewater and resultant serosols were sampled and analyzed. Fluorescent dye studies were also performed to characterize the aerosol cloud without the effects of biological decay. During all of the aerosol tests continuous on-site meteorological measurements were made and wastewater chemical parameters monitored.

TEST OF SNOW FORTIFICATIONS.

Farrell, D.R., Oct. 1979, 15p., ADA-078 742, 16 refs.

PENETRATION TESTS, MILITARY ENGINEER-ING, SNOW (CONSTRUCTION MATERIAL), FORTIFICATIONS, SMALL ARMS AMMUNI-TION

TION.

A field study was conducted to 1) more accurately define the degree of protection offered by simple snow fortification and 2) evaluate the effort required by infantry troops to build such fortifications when only basic tools are available. A seven-man infantry squad, equipped with standard issue snow shovels and an arctic sled (Akhio), constructed several simple snow structures. Construction was made more difficult by the imposition of a camouflage discipline requirement. When completed, three positions were subjected to M16Ai rifle fire while the infantry squad executed a simulated tactical facult by the imposition of a camouflage discipline requirement. When completed, three positions were subjected to M16Ai rifle fire while the infantry squad executed a simulated tactical assault. A fourth and much larger position was tested with simulated covering fire from a M2HB 50-caliber machine gun. None of the 5.56-mm bullets fired by the squad from ranges of 200 m to as close as 10 m managed to penetrate the 1.8-m-thick snow embankments. The 12.7-mm-diameter bullets fired from the M2HB at a range of 250 m were all stopped by 3.0 m of packed snow. The camouflage considerations and the shallow snow conditions increased the construction time for the three small emplacement by almost a factor of four, and for the larger emplacement increased the construction time for the three small emplacements by almost a factor of four, and for the larger emplacement by almost a factor of three. But the squad still handled a volume of packed anow that was equal to 3.7 times the volume of unfrozen soil that could be handled with the same amount of effort, according to field manual estimates. Under frozen soil conditions the advantages of using snow would be significantly greater.

UTILIZATION OF SEWAGE SLUDGE FOR TER-RAIN STABILIZATION IN COLD REGIONS. PT. 3.

Rindge, S.D., et al, Oct. 1979, 33p., ADA-077 585. Gaskin, D.A., Palazzo, A.J.

34-2365

WASTE DISPOSAL, SEWAGE DISPOSAL, SOIL STABILIZATION.

The authors have conducted a two-year revegetation study to assess the ability of sewage sludge applications with or without supplemental fertilizer to promote plant growth and stabilize alongs soils. The study site was a west-facing, 16 deg slope at CRREL in Hanover, New Hampshire. 16 deg alope at CRREL in Hanover, New Hampshire. Bight revegetation treatments and one control were replicated three times. Treatments involved applications of dewatered, anserobically digested sewage sludge at two rates (20 or 40 tom/scre). The sludge was applied alone or in combination with commercial fertilizers which supplied nitrogen, phosphorus and potassium, or all three nutrients. The seed mixture in the treatments contained four grasses and one legume. The effects of the various treatments were determined through soil loss yields, visual grass ratings and plant vields.

PROTOTYPE OVERLAND FLOW TEST DATA: JUNE 1977-MAY 1978.

Jenkins, T.F., et al, Nov. 1979, 91p., ADA-078 743, 9 refs.

rets. 34-1599 WASTE TREATMENT, WATER TREATMENT, IRRIGATION, SOIL CHEMISTRY, ION EX-CHANGE, METEOROLOGICAL DATA.

A prototype overland flow land treatment system was operated at Hanover, New Hampshire, over a one-year cycle from June 1977 to May 1978. The individual data points collected awar 1971/10 May 1978. In mountaind data points collected over this period for water quantity and quality are presented, as well as plant yields and nutrient uptake. The soil chemical and physical parameters measured are also presented along with a table of initial site characteristics. The meteorological measurements obtained in support of this effort are included to complete the data base.

PROCEEDINGS OF A MEETING ON MODEL-ING OF SNOW COVER RUNOFF, 26-28 SEP-TEMBER 1978, HANOVER, NEW HAMPSHIRE. Colbeck, S.C., ed, Jan 1979, 432p., ADA-167 767, For individual papers see 34-1002 through 34-1040. Nu-merous refs.

WASTE TREATMENT, WATER TREATMENT, MICROWAVES, BACTERIA.

Results from a laboratory study show that microwave energy can be used for disinfection of wastewater. The time required for destruction of bacteria by microwaves was reduced over that of conventional heating.

Destruction of wastewater

bacteria and a cell-suspension of of *E. Coli B.* was logarithmic after an initial lag phase, which was dependent upon the volume used. Thermophilis *B. stearothermophilus* cells were used to try to determine if the mechanism of destruction

ICEBREAKING CONCEPTS.

Mellor, M., Jan. 1980, 18p., ADA-082 175, 4 refs.

ICE BREAKING, ICEBREAKERS, ICE COVER THICKNESS, PENETRATION, ICE CUTTING, ICE BLASTING, MARINE TRANSPORTATION, OFFSHORE STRUCTURES.

OFFSHORE STRUCTURES.

Icebreaking concepts that have potential application in the protection of offshore stuctures and drillships are reviewed. The concepts dealt with include conventional icebreaking by ships, icebreaking by air cushion vehicles, breaking against fixed structures, mechanical cutting with drag bit tools, blasting by high explosives, blasting with compressed gases or propellants, ice melting, thermal cutting, cutting with liseers, cutting with high pressure water jets, and unproven novel concepts. Special emphasis is given to the specific energy requirements for the various methods.

DANISH DEEP DRILL; PROGRESS REPORT: FEBRUARY-MARCH 1979.

Rand, J.H., Jan. 1980, 37p., ADA-082 206.

DRILLING, ICE CORING DRILLS, ICE CORES, GLACIOLOGY, DESIGN, PERFORMANCE, GLACIOLOGY, MAINTENANCE.

MAINTENANCE.

The "Danish Deep Drill" was developed at the University of Copenhagen. The drill, which will be used to obtain ice cores from the Greenland Ice Sheet, was tested at the U.S. Army Cold Regions Research and Engineering Laboratory.

The drill is battery-operated and has a down-hole microprocessor-based control section and a delicately balanced chip removal system. It is a lightweight, electro-mechanical drill designed to obtain a 10.2-cm-dismeter core in 2-m lensths. There are notential problems in chip recovery drill designed to obtain a 10,2-cm-diameter core in 2-m lengths. There are potential problems in chip recovery and storage, malfunctions of the computer or batteries, leaks in the pressure chamber, spin-out or rotation of the drill, and the very close tolerances required by the drill design. Tests are recommended that will help eliminate some of these potential problems and determine the drill's overall strengths and weaknesses. The drill is a very complex and delicate instrument that will require constant maintenance, modification and monitoring when in use.

SR 80-04

EVALUATION OF ICE DEPLECTORS ON THE USCG ICEBREAKER POLAR STAR. Vance, G.P., Jan. 1980, 37p., ADA-082 205. 35-2595

ICEBREAKERS, PROPELLERS. ICE COVER THICKNESS, ICE NAVIGATION.

THICKNESS, IČE NAVIGATION.

Model tests were carried out in the CRREL Ice Engineering Facility test beain on a 1-to-19.1 model of the USCG Polar Star (WAGB-10) to determine the effectiveness of several different devices that would eliminate or mitigate the ingestion of ice into the propeller slip stream. Propeller RPM records and highspeed movies were obtained for each device in two thicknesses of ice and at two speeds. Four devices were evaluated: large bilge keels, small bilge keels, bossing fins and propeller cages (called bird cages). The most effective concept appeared to be the bilge keels. Open water power tests and structural analysis must now be carried out to determine the overall feasibility of these concepts. SR 80-05

COASTAL ENVIRONMENT, BATHYMETRY, AND PHYSICAL OCEANOGRAPHY ALONG THE BEAUFORT, CHUKCHI AND BERING

Gatto, L.W., Jan. 1980, 357p., ADA-084 281, 56 refs.

COASTAL TOPOGRAPHIC FEATURES, BATH-YMETRY, MARINE GEOLOGY, SHORELINE MODIFICATION, OCEANOGRAPHY, ENVI-RONMENTS.

The report compiles references, figures, and tables that are concerned with the coastal environment, bathymetry, and physical oceanography along the Beaufort, Chukchi, and Bering Seas. The text, intentionally minimized, describes the salient points with a minimum of detail. The extensive references and figures give direction to a reader seeking additional information.

POST OCCUPANCY EVALUATION OF A PLANNED COMMUNITY IN ARCTIC CANADA. Bechtel, R.B., et al, Feb. 1980, 27p., ADA-082 162, 4 refs.

Ledbetter, C.B.

35-2596 URBAN PLANNING, HOUSES, SITE SURVEYS, BUILDINGS, ECOLOGY.

This report describes a post-occupancy evaluation of a small mining community in the high Arctic. Providing superior housing, having wives work and integrating singles, inuit (the indigenous people) and families successfully established a viable community. Pewer problems were encountered than is usual in other isolated cold regions communities.

The central focal point of the town, a large dome, was diluted by later construction of buildings housing separate recreational and social facilities. Since the buildings are too costly to remove, the only method of restoring the focal point is to build connecting links at upper levels of the recreational buildings.

SOME ASPECTS OF SOVIET TRENCHING MA-CHINES

Mellor, M., Feb. 1980, 13p., ADA-082 176, 1 ref. 35-2597

TRENCHING, FROZEN GROUND, EARTH-WORK, EQUIPMENT, DESIGN.

Technical characteristics of Soviet trenching machines are assessed and compared with those of similar machines built in the United States and Europe. The report deals with transverse rotation machines and belt machines, considering transverse rotation machines and belt machines, considering rotor speeds and belt speeds, tool speeds, power /weight ratios, power density, traverse speeds, and effective mean cutting pressures. The probable capabilities of Soviet machines for cutting frozen ground are assessed. It is concluded that, while general design characteristics are satisfactory, construction and product development are weak, and performance in frozen ground is not expected to be impressive.

DOCUMENTATION FOR A TWO-LEVEL DY-NAMIC THERMODYNAMIC SEA ICE MODEL. Hibler, W.D., III, Feb. 1980, 35p., ADA-084 273, 9

34-3329

SEA ICE, ICE THERMAL PROPERTIES, THER-MODYNAMIC PROPERTIES, HEAT TRANS-FER, ICE MECHANICS, ICE COVER THICK-NESS, MATHEMATICAL MODELS, COMPUTER PROGRAMS, RHEOLOGY.

PROGRAMS, RHEOLOGY.

A discussion of the numerics and computer code for a two-level dynamic thermodynamic sea ice model is presented. For interested users a listing of the computer code and results from a 21-day test run are included as appendices. To a large degree this report is meant to serve as an extended appendix to an article by the author in the Journal of Physical Oceanography (see 34-741) describing his model and a variety of simulation results. The model consists of a two-level ice thickness distribution coupled to the ice dynamics by a plastic rheology. In addition to the ice intersection, the momentum balance includes nonlinear wind dynamics by a plastic rheology. In addition to the interaction, the momentum balance includes nonlinear w and water drag terms, Coriolis force, and inertial and mom and water drag terms, Coriolis force, and inertial and momen-tum advection terms. The numerical scheme is formulated in an energy-conserving manner in a fixed Eulerian grid which allows simulation over unlimited time intervals. The momentum balance (including inertial terms) is numerically treated in a semi-implicit manner so that time steps of up to one day in length may be used if desired. The boundariea, grid size and time step magnitude are easily modified so that the model should have application to a variety of climate and forecasting problems.

SR 80-09

THICKNESS-TENSILE STRESS RELA-TIONSHIP FOR LOAD-BEARING ICE. Johnson, P.R., Feb. 1980, 11p., ADA-084 274, 3 refs.

ICE COVER STRENGTH, ICE LOADS, ICE CROSSINGS, ICE ROADS, TENSILE PROPERTIES, STRESSES, ICE COVER THICKNESS.

TIES, STRESSES, ICE COVER THICKNESS.

The "bearing capacity" of a floating ice sheet is of considerable interest. The pattern of ice thickness vs tensile stress for a fixed load and fixed ice properties was examined and showed some constant relationships. It proved possible to completely describe the ice thickness-tensile stress pattern in terms of a single number. When the load was changed by increasing the payload but not altering the geometry of the load pattern, other relationships were found that described the tensile stress in the ice sheet for any combination of payload and ice thickness. This provides a simple method of finding tensile stress in the ice that can be used in the field. Further studies are planned.

OPERATION OF THE CRREL PROTOTYPE AIR TRANSPORTABLE SHELTER. Flanders, S.N., Feb. 1980, 73p., ADA-084 275.

PORTABLE SHELTERS, COLD WEATHER PER-FORMANCE, TRANSPORTATION, AIR-PLANES, LOGISTICS.

PLANES, LOGISTICS.

This report describes the operation of the CRREL prototype air-transportable shelter which was designed specifically for use in cold regions. The operating instructions cover moving the shelter on its own wheels or skin, loading it onto a truck or military transport aircraft, slinging it from a helicopter or preparing it for shipment as an ISO container. The report details how to site the shelter and expand it to about double its transport size. The report also covers operation of the utility systems, including the on-board alternator set, the primary and auxiliary heating systems, the water system, and various safety systems.

SR 80-11 SNOW FORTIFICATIONS AS PROTECTION AGAINST SHAPED CHARGE ANTITANK PRO-**JECTILES**

Farrell, D.R., Mar. 1980, 19p., ADA-084 276. 14.3332

SNOW STRENGTH, FORTIFICATIONS, COLD WEATHER CONSTRUCTION, COLD WEATHER OPERATION, SNOW (CONSTRUCTION MATERIAL), EXPLOSION EFFECTS, IMPACT MATERIAL), EXPLOSION TESTS, DETONATION MENTS.

This report chronicles an investigation of the effectiveness of snow fortifications. The test was planned to observe and measure how packed snow absorbs the energy of high explosive antitank (HBAT) ammunition. In the test plan both the possibility of non-detonation due to insufficient resistance in snow and the rate of deterioration of a snow reassance in snow and the rate of deterioration of a snow embankment with repeated impacts were considered. The 90-mm M67 recoilles rifle was used because it has a relatively low velocity, and its charge was more likely to not detonate than that of a high velocity weapon. The findings indicate that snow can be used to good advantage for building expedient fortifications, particularly in situations where large volumes of snow have to be cleared from roads and airfields.

SR 80-12 DRILLING AND CORING OF FROZEN GROUND IN NORTHERN ALASKA, SPRING

Lawson, D.E., et al, Mar. 1980, 14p., ADA-084 277,

Brockett, B.E.

DRILLING, PERMAFROST STRUCTURE, STRA-TIGRAPHY, GROUND ICE, PERMAFROST SAMPLERS, CORE SAMPLERS, EQUIPMENT.

Frozen samples of perennially frozen ground were obtained from 33 holes drilled at six locations in the National Petroleum Reserve, Alaska, in the spring of 1979. Total depth of drilling was 510 m (1670 ft), of which 178 m (384 ft) was cored. The objectives of the program were to define the location and extent of segregated and massive ice at each location and to determine the origins and ages of the ground ice through studies of the hole stratigraphy and future laboratory analyses of core samples.

EXTENDING THE USEFUL LIFE OF DYE-2 TO 1986. PART 2: 1979 FINDINGS AND FINAL RECOMMENDATIONS.

Tobiasson, W., et al, Apr. 1980, 37p., ADA-084 278, 8 refs.

Tilton, P. 34-3334

34-33-34
RADAR, STATIONS, SNOW ACCUMULATION, ICE FORMATION, SNOW STRENGTH, LOADS (FORCES), STEEL STRUCTURES, STRESSES, COST ANALYSIS.

COST ANALYSIS.

A major construction effort is needed at Dew Line Ice Cap Station DYE-2 to extend its useful life to 1986. That work should be done as soon as possible because the truss enclosure is deteriorating rapidly. Although a 210-ft sideways move as was accomplished at DYE-3 in 1977 is technically feasible, the alternative of backfilling the truss enclosure with ice is expected to cost about \$2.7 million less. Unless there is a strong possibility that DYE-2 will be needed for many years beyond 1986, the ice backfill alternative is recommended.

CRREL ROOF MOISTURE SURVEY, PEASE AFB BUILDINGS 35, 63, 93, 112, 113, 120 AND

Korhonen, C., et al, Mar. 1980, 31p., ADA-084 279, 3 refs.

34-3335 ROOFS, MOISTURE TRANSFER, DETECTION, INFRARED SPECTROSCOPY, THERMAL INSU-LATION, MEASURING INSTRUMENTS.

We surveyed the roofs of seven buildings at Pease AFB with a hand-held infrared scanner to detect wet insulation. We used white spray point to outline the wet areas and took core samples of the built-up membrane and insulation to verify our findings. Flashing defects around penetrations and bordering walls appear to be the major cause of the wet insulation found on these roofs. Since most problem acreas are localized, we directed our regrets recommendations areas are localized, we directed our repair recommendations toward salvaging as much of each roof as is economically

SR 80-15 REGIONAL DISTRIBUTION AND CHARAC-TERISTICS OF BOTTOM SEDIMENTS IN ARC-TIC COASTAL WATERS OF ALASKA. Sellmann, P.V., Apr. 1980, 50p., ADA-084 922, Refs.

35-2598

SUBSEA PERMAFROST, PERMAFROST DISTRI-BUTION, BOTTOM SEDIMENT, MARINE GEOLOGY, SEDIMENT TRANSPORT, PERMA-FROST DEPTH, ICE SCORING, OFFSHORE STRUCTURES, ARTIFICIAL ISLANDS, CONSTRUCTION MATERIALS, OFFSHORE DRILL

This report includes a discussion of some of the properties and characteristics of offshore marine sediments found in the U.S. Beaufort Sea that could influence aspects of offshore development. A collection of references is also included in an appendix. Perennially and seasonally frozen sediments are extremely common, with variable distribution and properties. The depth to the top of lockonded permatrost can be as little as 7 m below the seabed many kilometers from the sea coast. The subsea permatrost can contain visible ground ice similar to that observed on land, and can be anticipated to cause problems at least as great as those experienced on land.

NITROGEN TRANSFORMATIONS IN A SIMU-LATED OVERLAND FLOW WASTEWATER TREATMENT SYSTEM.

Chen, R.L., et al, Apr. 1980, 33p., ADA-084 280, 36

Patrick, W.H., Jr.

WASTE TREATMENT, WATER TREATMENT, NUTRIENT CYCLE, SOIL CHEMISTRY.

NUTRIENT CYCLE, SOIL CHEMISTRY.

Treating wastewater in properly designed and operated overland flow systems results in significant amounts of N being
removed through nitrification-denitrification reactions. Application of wastewater containing NH4-N in a simulated
overland flow model led to the disappearance of sumonium
and the formation of nitrate in oxidized surface soil. The
N balance in the simulated overland flow system was estimated
by using labeled 15 N. The amount of N removed in
the system depends upon denitrification rates. The results
of this study indicated that N adsorption on the soil complex
and uptake of applied ammonium by vegetation accounted
for the N removed in the overland flow systems. The
adsorbed ammonium on the serated surface soil mass was
nitrified and converted to oxidized forms of N. The
nitrate thus formed diffused downward to the reduced zone
during subsequent wastewater applications. Some of this
nitrate then denitrified and converted to gaseous form of
N or was assimilated and reduced by plant life. Results
of the overland flow studies indicated that approximately
55-68% of wastewater NH4-N added to the simulated overland
flow system was unaccounted for in controlled laboratory m was unaccounted for in controlled laboratory nts. This NH4-N was presumably returned to

INFLUENCE OF NOSE SHAPE AND L/D RATIO ON PROJECTILE PENETRATION IN FROZEN SOIL.

Richmond, P.W., Apr. 1980, 21p., ADA-085 398, 10

FROZEN GROUND, PROJECTILE PENETRA-TION, SOLUTIONS, EXPERIMENTATION.

This report presents the results of a laboratory test program designed to determine the applicability of two analytical solutions to projectile penetrations in frozen soils. The test program consisted of firing small caliber cylindrical projectiles into frozen soil targets. Four types of 7.9-mm-diam receivables were nested. icas program consisted of firing amail caliber cylindrical projectiles into frozen soil targets. Four types of 7.9-mm-diam projectiles were tested: two with a hemispherical nose the other two flat-nosed, with both long (length/diameter = \pm 4) and short (L/D = 2) versions of each nose shape. Prestion depth versus impact velocity data are presented. Comparisons of the data indicate that a flat-nosed projectile is a less efficient penetrator than one of equal weight with a hemispherical nose. A small increase in resistance to penetration is observed for an increased L/D ratio.

TURE, TESTS.

This paper presents the construction procedure, data and snalysis from an experimental field program to determine the rippability and compaction characteristics of frozen soil. Also investigated was the stability upon thawing of the frozen soil compacted in the field. From the results of the experimental program, several important conclusions concerning winter earthwork were obtained. 1) Ripping frozen soil can be accomplished with heavy equipment which will produce a large range of chunk sizes. 2) The effectiveness of field compaction of frozen material is highly dependent on the mosture content of the soils. 3) The magnitude of settlement in embankments constructed of frozen material is closely related to the compacted dry density of the placed soil.

SR 80-22 ESTIMATING COSTS OF ICE DAMAGE TO PRI-VATE SHORELINE STRUCTURES ON GREAT LAKES CONNECTING CHANNELS. Carey, K.L., May 1980, 33p., ADA-089 781. 35-2599

STRUCTURES, DAMAGE, ICE LOADS, IMPACT STRENGTH, ICE PRESSURE, ICE NAVIGA-TION, COST ANALYSIS.

Tion, Cost Anal. 1818.

The possible extension of the navigation season through the entire winter or a portion thereof has been under consideration for the Great Lakes and the St. Lawrence Seaway for a number of years. To balance the benefits and costs of such an extension it is necessary to determine the damage costs to shore structures that might result from ice loosened by ship passage. This paper is concerned with the interconceting channels of the Lakes where there is estimated to be \$18,000,000 (1976 dollars) worth of small, private, vulnera-

1) to obtain information

CLE, AGRICULTURE.

The objectives of this field study were 1) to obtain information on the dynamic behavior of wastewater NH4 and NO3 in soils, 2) to determine the relative abundance of NH4 and NO3 in soils receiving wastewater, and 3) to evaluate the seasonal effect on the fate of wastewater NH4 applied to soils in a slow infiltration system. The study was conducted using an on-going test plot which contained two soil types and was covered with forage grass. Samples were collected in June and October to study the seasonal effect on the dynamic of N. The concentrations of NH4 and NO3 in the soil reached a daily, quasi-steady state condition. The seasonal effect on the relative amounts of NH4 and NO3. The concentrations of both NH4 and NO3. The concentrations of both NH4 and NO3 in profile were high at the surface and decreased with depth, consistent with the higher organic matter content in the surface. Both NH4 and NO3 concentrations were higher in the finer texture Charlton silt loam soil than in the coarser texture Windsor sandy loam soil.

SR 80-28 ICE ADHESION TESTS ON COATINGS SUB-JECTED TO RAIN EROSION. Minsk, L.D., July 1980, 14p., ADA-089 698.

TIVE COATINGS, HELICOPTERS, TESTS.

TIVE COATINGS, HELICOPTERS, TESTS. Screening tests to select icephobic coatings displaying low ice release forces, both before and after exposure to rain erosion in a whirling arm simulator, were performed on approximately 60 commercial materials. A unique linear ball-slide shear test apparatus was designed to provide pure shear forces. No coating survived the erosion test to give an interfacial shear strength as low as 15 psi (103 kPa), an arbitrarily established goal. Several coatings showed shear strengths between 30 and 45 psi (207 and 310 kPa) after rain erosion.

SR 86-29
POST OCCUPANCY EVALUATION OF A
REMOTE AUSTRALIAN COMMUNITY: SHAY
GAP, AUSTRALIA.

Bechtel, R.B., et al, July 1980, 57p., ADA-089 675, 8

Ledbetter, C.B.

35-2600 URBAN PLANNING, HOUSES, BUILDINGS, SITE SURVEYS, ECOLOGY.

SITE SURVEYS, ECOLOGY.

A post occupancy evaluation (POE) was made of Shay Gap, an iron mining community in Western Australia. More than 50 design hypotheses were tested with results favoring the original design. Selecting a townsite surrounded by hills was deemed successful by residents. Keeping automobiles out of the living areas increased the safety of children and made residents walk and socialize more. A centrally located building housing the shopping facilities, beauty parior, bank, poet office, and mack bar served as the foculation of the community. Bland, off-white interiors allowed residents to express themselves when decorating. Shay Gap was a successful design concept for communities designed for remote areas in either hot or cold regions.

SR 80-30 DYNAMIC TESTING OF FREE FIELD STRESS GAGES IN FROZEN SOIL.

Aitken, G.W., et al, July 1980, 26p., ADA-089 676, 6

Albert, D.G., Richmond, P.W. 35-2601

FROZEN GROUND MECHANICS, STRESSES, IMPACT TESTS, SHOCK WAVES, SOIL ME-CHANICS, WAVE PROPAGATION.

CHANICS, WAVE PROPAGATION.

This report describes an attempt to develop a procedure for dynamic calibration of free-field soil stress gages embedded in a soil sample. The method presented utilizes a droptype impact testing machine and a small, instrumented container of soil. The velocity history of a shock pulse applied to the soil sample is measured and the applied stress computed; this value is then compared with data obtained from stress gages embedded in the soil. The results showed that the procedure is adequate for unfrozen soil, but for frozen soil the accuracy in the measurement of compressional wave velocity needs to be increased to obtain useful results.

REVIEW OF TECHNIQUES FOR MEASURING SOIL MOISTURE IN SITU.

McKim, H.L., et al, Aug. 1980, 17p., ADA-089 974, Refs. p. 13-17. Walsh, J.E., Arion, D.N.

35-976 SOIL WATER, ELECTROMAGNETIC PROPERTIES, TENSILE PROPERTIES, CLIMATIC FAC-TORS.

TORS.
Recently there has been an increased interest in the insitu measurement of soil moisture content in the areas of hydrology, meteorology, agriculture and environmental studies. Current methods generally have limitations, depending upon the use of the data, that greatly influence acquisition and reliability of the soil moisture determination. This report discusses gravimetric, nuclear, electromagnetic, tensiometric and hygroscopic techniques and the advantages and disadvantages of using the techniques. Emphasis is placed on the tensiometric and electromagnetic techniques. These two measurements when coupled would supply information on the wetting and drying soil moisture characteristic curves and thereby provide a means of tracing moisture movement under field conditions in cold climates.

CHARACTERISTICS OF ICE IN WHITEFISH BAY AND ST. MARYS RIVER DURING JANU-ARY, FEBRUARY AND MARCH 1979. Vance, G.P., Aug. 1980, 27p., ADA-089 950, 12 refs.

COVER STRENGTH, FLEXURAL STRENGTH, ICE DENSITY, METAL ICE FRICTION, METAL SNOW FRICTION, SNOW DENSITY, SNOW DEPTH, AIR TEMPERATURE.

DEPTH, AIR TEMPERATURE.
This report presents data on the full-scale trials of the U.S. Coast Guard loebreaker Katunai Bay, which was tested in plate ice that varied in thickness from 10 to 33 in. (25.4 to 83.82 cm) and had a snow cover of 1 to 6 in. (2.54 to 15.24 cm). In January the average temperature was -SC, and the ice flexural strength was 13,363 lb/sq.ft (640 kPa). In March the average temperature was -2C and the ice flexural strength was 11,643 lb/sq. ft (560 kPa). The specific weight (density) of the ice was 0.894 g/cu cm. The specific weight of the snow was in the area of 0.32 g/cm. The coefficient of friction between the ice/snow and steep lpate (coated and uncoated) varied from a low of 0.02 in the dynamic case of ice on the Inerta 160 coating to 0.47 for the static case of snow on a rusty steel plate.

SR 80-33 NEW HAMPSHIRE FIELD STUDIES OF MEM-BRANE ENCAPSULATED SOIL LAYERS WITH ADDITIVES.

SOIL FREEZING, FROST PENETRATION, SOIL STABILIZATION, SOIL WATER, FROST RESIST-ANCE, PAVEMENTS, ADMIXTURES, LIMING,

DESIGN.
This report describes the construction, instrumentation, and performance of membrane encapsulated soil layer (MESL) pavement test sections at the U.S. Army Cold Regions Research and Ragineering Laboratory in Hanover, New Hampshire, from 1973 to 1978. Membrane encapsulated soil layer construction involves using a waterproof membrane to protect low grade soils from absorbing moisture, especially during the freezing process. Most of these lower grade soils are frost-susceptible; in these soils water can be drawn to the freezing zone to form ice lenses, which in turn cause heaving of the surface. Lime, flyash, and sodium chloride were added to a silt material prior to encapsulation. These additives were incorporated to add strength to the silt, absorb excess moisture, and increase its load-supporting capabilities. Results show that 1) the moisture content within the MESL. sections remained relatively constant over the five years of testing, 2) a nonencapsulated lime-flyash-stabilized silt sections remained relatively constant over the five years of testing, 2) a nonencapsulated time-flyash-stabilized sitt material heaved 8.8 times as much as the identical material which was encapsulated, 3) the lime-flyash-stabilized MESL, had twice the strength of the plain or sali-stabilized MESL, 4) the sift with the additives had less frost heave within the MESL than the untreated silt. In summary, MESL's can be constructed to perform well in cold regions, thereby replacing high quality aggregates which are being depleted.

SR 80-34 DESIGN AND CONSTRUCTION OF FOUNDA-TIONS IN AREAS OF DEEP SEASONAL FROST AND PERMAPROST.

CHARACS, DESIGN.

This report presents engineering guidance for the design and construction of foundations in areas of deep seasonal frost and permafrost as developed up to the early 1970's. Attention is given to basic considerations affecting foundation design, site investigations, survey datum points, construction considerations, and monitoring performance. Included in the main text are 17 tables, 141 figures, and 213 selected references.

A bibliography presents 45 additional references.

RESINS AND NON-PORTLAND CEMENTS FOR CONSTRUCTION IN THE COLD. Johnson, R., Sep. 1980, 19p., ADA-092 952, 6 refs.

CEMENTS, COLD WEATHER CONSTRUCTION, CONSTRUCTION MATERIALS, POLYMERS.

A laboratory investigation was conducted to assess the potential A laboratory investigation was conducted to assess the potential of some resins and non-portland cements for structural concerted at low temperatures. The resins investigated were urethane (non-hydrophilic), epoxy and polyester, as well as a polysulfide polymer. Two non-portland (modified) cements were also tested. The curability of the resins, when mixed with fine aggregate, showed that they had potential for low temperature use in the following decreasing order: urethane, polyester, and epoxy. Of the non-portland cement materials, mixed as individual nest sluving one showed potential for low and epoxy. Of the non-portland cement materials, mixed as individual neat alurries, one showed potential for low temperature use at -10 C (using 3.9 C water).

SR 80-36 INFILTRATION CHARACTERISTICS OF SOILS AT APPLE VALLEY, MINN.; CLARENCE CANNON DAM, MO; AND DEER CREEK LAKE, OHIO, LAND TREATMENT SITES.

Knowledge of the thermal diffusivity of frozen soils is nece for transient heat transfer analysis. The specific heat, thermal conductivity and density for a sand, a silt and a clay were obtained experimentally and used to calculate their thermal diffusivity. These properties were measured their thermal diffusivity. These properties were measured over a range of temperatures from -50 C to +45 C and for moisture contents from dry to saturated. The use of a differential scanning calorimeter for obtaining specific heat values was proven to be a reliable technique.

STRUCTURAL EVALUATION OF POROUS PAVEMENT TEST SECTIONS AT WALDEN POND STATE RESERVATION, CONCORD, MASSACHUSETTS.

LOADS (FORCES), DEFORMATION, TESTS. This report presents the results of repeated load tests upon various porous pavement test sections constructed in an overflow parking lot at Walden Pond State Reservation in Concord, Massachusetts. From the fall of 1977 to the spring of 1979, the seasonal structural responses of the sections were monitored with a repeated plate bearing apparatus. After the first set of fall and spring tests, some sections were reconstructed because the asphalt concrete pavement was not porous enough. Test points were added or replaced to accommodate the reconstructed sections. Results show that the dense asphalt concrete distributed the load over to accommodate the reconstructed sections. Results show that the dense asphalt concrete distributed the load over a greater area than the porous asphalt concrete, thicker pavements were stronger for both dense and porous asphalt concrete, and the deflection basin depth and diameter changed proportionately to applied loads.

OVERLAND FLOW: REMOVAL OF TOXIC VOLATILE ORGANICS.

Jenkins, T.F., et al, Feb. 1981, 16p., ADA-097 576, 34

Leggett, D.C., Martel, C.J., Hare, H.E. 35-2581

WASTE TREATMENT, WATER TREATMENT, FLOODING, LAND RECLAMATION, WATER CHEMISTRY.

A small-scale overland flow system was studied to determine its effectiveness in reducing the levels of volatile trace organics in municipal wastewater. Chlorinated primary wastewater, water collected from the surface at various points downslope, and runoff were analyzed by gas chromatography/mass spectrometry using a purge and trap sampler. The results indicated that overland flow was effective in reducing the levels of these substances by 80-100% depending on the specific substance and the application rate. The removal mechanism was found to follow first order kinetics. The second little mechanism to exhibit the observed behavior its effectiveness in reducing the levels of volatile trace org mechanism was found to follow first order kinetics. The most likely mechanism to explain the observed behavior is volatilization. Comparison of the experimental results with theoretical prediction using published models resulted in reasonable agreement considering the complexity of the system compared to the model systems.

METHOD FOR COINCIDENTALLY DELER-MINING SOIL HYDRAULIC CONDUCTIVITY AND MOISTURE RETENTION CHARACTERIS-

SNOW STRENGTH, COMPRESSIVE PROPERTIES, SNOW DENSITY, LOADS (FORCES), SNOW DEPTH, DRILL CORE ANALYSIS.

SNOW DEPTH, DRILL CORE ANALYSIS.

Snow samples from five 50-ft (15.2m) deep holes, augered adjacent to the west side of DEW line Station Dye-2 in Greenland, were investigated for density and unconfined compressive strength. Forty-two percent of the recovered cores were tested. Ninety-three percent of the samples tested had a length/diameter ratio greater than 2:1. The loading rate was 2 in./min (51 mm/min). Sample endeffects appeared to influence a high percentage of the failures. The heavily disturbed nature of the material is evidenced in the widely scattered values of density and strength with depth. A minimum and maximum strength value of 31 psi (0.21 MPa) and 1055 psi (7.34 MPa) respectively were obtained from a hole located 50 ft (15.2 m) from the structure. Using an approach similar to that used prior to the Dye-3 move in 1976, a safety factor exceeding 6.5 is obtained against a brittle bearing failure based on a maximum footing design load of 2000 lb/sq ft (96 kPa).

GRAVEL, NUTRIENT CYCLE.

Two greenhouse studies were performed with gravel soils to determine the requirements for nitrogen (N), phosphorus (P), and potassium (K) for grass establishment and to assess the establishment performance of 15 types of grasses. The fertilizer study consisted of 30 treatments, each representing a different combination of application rates of N, P, and K. A seed mixture containing "Nugget" Kentucky bluegrass, "Penniswn" rod fescue, and annual ryegrass was sown, and the plants were harvested 133 days after sowing. Plant leaf and root weights were measured, and soil samples were analyzed for pH, P, K and soluble salts. In the grass study, 15 grasses were grown for 76 days. All treatments

were fertilized at the beginning of the study. Plant establishment was periodically assessed and yields were measured at the end of the study. In the fertilizer study, N and P were shown to be limiting to leaf growth on this soil. Applications of P were the most beneficial for root growth. Needs for K were less evident, but it was required for Applications of P were the most beneficial for root growth. Needs for K were less evident, but it was required for maximum leaf growth at the higher application rates of N and P. The greatest yields were recorded when all three elements were applied, while at the lower application rates only N and P were required to promote growth. SR 81-05

OPPER OCEAN TEMPERATURE, SALINITY AND DENSITY IN THE VICINITY OF ARCTIC DRIFT STATION FRAM 1, MARCH TO MAY

SUBLIMATION, PERM. TION, DUST CONTROL. PERMAFROST PRESERVA-

The U.S. Army Cold Regions Research and Engineering Laboratory's permafrost tunnel at Fox, near Fairbanks, Alaska, Laboratory's permafrost tunnel at Fox, near Fairbanks, Alaska, was used to investigate the sublimation process in permafrost silt. The rate of increase in thickness of the dried silt layer from sublimation was found to be approximately 0.023 in. (0.058 cm) in I month and closely related to the relative humidity in the tunnel. Sublimation prevention studies consisted of evaluation of various membranes to impede the sublimation. Ice was found to show promise as an easily installed, effective membrane when applied as a fine water mist and subsequently left to freeze.

SR 81-09 ICE JAM PROBLEMS AT OIL CITY, PENNSYL-

Deck, D.S., et al, May 1981, 19p., ADA-103 736, 9 refs.

36-179 ICE JAMS, FLOOD CONTROL, ICE CONDI-TIONS.

Oil City, Pennsylvania, is at the confluence of Oil Creek and the Allegheny River. The business district lies within the flood plain of Oil Creek, and as of the winter of 1980, 25 ice jam flooding events had occurred since the mid-

1800's. An investigation was done to determine why Oil City was subject to perennial ice jams and nearly biennial ice jam floods. Ice conditions were analyzed and it was determined how and why the jams occurred. By controlling where the initial ice cover forms, Oil City's ice jam floods can be alleviated. Ice control structures will be used to encourage the early formation of ice cover and hence eliminate frazil ice. This will greatly reduce the amount of ice which currently develops in both Oil Creek and the Allegheny River.

FABRIC INSTALLATION TO MINIMIZE RE-FLECTION CRACKING ON TAXIWAYS AT THULE AIRBASE, GREENLAND. Baton, R.A., et al, May 1981, 26p., ADA-103 737, 2

ICE COVER EFFECT, CHANNELS (WATER-WAYS), COAL, FUEL TRANSPORT, LOCKS (WATER-WAYS), MARINE TRANSPORTATION, COLD WEATHER PERFORMANCE, DAMS.

COLD WEATHER PERFORMANCE, DAMS.
The part of the Inland Waterways which carries significant coal and which may experience significant ice problems includes the following rivers or waterways: Ohio, Monogahela, Allegheny, Kanawha, Upper Mississippi, and Illinois. Coal transportation along these rivers may be locally interrupted for periods up to 30 days or more every three to five years. Coal handling facilities, navigation channels, and lock and dam sites along the ice prone rivers were surveyed by visit or telephone to ascertain the acope of the ice problems. The importance of ice as a barrier to increased coal movement on the waterways studied manifests itself differently for each link of the flow system. In order of importance the ice will affect the navigation channels, locks and dams, and finally the coal loading unloading facilities. The coal handling facilities will not be significantly slowed down by ice problems associated with winter navigation.

SR 81-14 LOSSES FROM THE FORT WAINWRIGHT HEAT DISTRIBUTION SYSTEM.

Phetteplace, G., et al, June 1981, 29p., ADA-103 741, 6 refs.

Willey, W., Novick, M.A.

Wiley, W., NOVIES, WARTS 36-351 HEAT LOSS, ELECTRIC POWER, PIPELINES, STEAM, THERMAL INSULATION, COMPUTER APPLICATIONS, ANALYSIS (MATHEMATICS). APPLICATIONS, ANALYSIS (MATHEMATICS). This report estimates the heat losses from the heat distribt ion system at Fort Wainwright, Alaska. Specific data on the Fort Wainwright heat and power plant are given and a method is then developed to calculate the heat losses from buried utilidor systems, such as the one at Fort Wainwright. This method is programmed for computer execution and estimates are made for the Fort Wainwright system, where heat losses are found to be 204,500 MBtv/yr. Possible improvements to the system to reduce heat losses are examined. Of the possible combinations of additional pipe insulation investigated, the addition of 1 in. of insulation to the steam pipe only is the most economically favorable. The results also indicate that insulating only the generally larger pipes found in larger utilidors would be the most economically favorable approach. Possible reductions in heat losses due to reduced steam temperature are also given, as well as recommendations for refinement of the predictions.

LIMNOLOGICAL INVESTIGATIONS: LAKE KOOCANUSA, MONTANA. PT. 5: PHOS-PHORUS CHEMISTRY OF SEDIMENTS.

Iskandar, I.K., et al, July 1981, 9p., ADA-107 049, 13

Shukla, S.S.

36-1122 LIMNOLOGY, LACUSTRINE DEPOSITS, CHEMICAL COMPOSITION, BOTTOM SEDI-

MENT. This study characterizes the aediments from Lake Koocanusa (Libby Dam reservoir), Montana, in terms of their ability to sorb and release P. Sediment samples were collected at 12 stations located between the U.S.-Canadian border and Libby Dam (42 miles downstream of the border) during July 1977. The sediments from Lake Koocanusa are calcarous, low in organic matter (< 2.3%), and have a sitty loam or loam texture. Most of the P associated with these sediments was in the inorganic form (> 85%), which was highly correlated (r=0.89) with oxalate extractable Fe in the sediment. Surption tests, with concentrations of either 1 or 10 mg P/g sediments, showed that these sediments have limited ability to sorb additional P from concentrated solutions. The maximum amount sorbed at the lower P concentrations was 67% of the added P and was highly correlated with oxalate extractable Fe in the sediments. Deoption studies showed that very small amounts of both conjustion with Damase extractance re in the sediments. Description studies showed that very small amounts of both the originally bound P (1 to 2%) and the added P (< 6.3%) were released. Conclusion: the sediments in Lake Koocanusa act as a P sink.

SR 81-16 PROCEEDINGS OF THE INTERNATIONAL SO-CIETY FOR TERRAIN-VEHICLE SYSTEMS WORKSHOP ON SNOW TRACTION MECHAN-ICS, ALTA, UTAH, JAN. 29-FEB. 2, 1979. Harrison, W.L., ed, July 1981, 71p., ADA-106 972, Refs. passim. For individual papers see 36-1391

Refs. passim. F through 36-1397. 36-1390

SNOW MECHANICS, SNOW COMPRESSION, TRACTION, TRAFFICABILITY, VEHICLE WHEELS, TRACKED VEHICLES, MEETINGS, MATHEMATICAL MODELS.

This report reviews the state of the art of snow traction mechanics and presents the results of a limited field exercise that allowed participants to observe and practice current snow measurement processes and vehicle test procedures. The prime recommendations of the workshop attendees were the use of parameters basic to the laws of physics for the classification of snow strength, and 2) the use of instrument-ed tracked and wheeled vehicles for snow strength measure-

MACROSCOPIC VIEW OF SNOW DEFORMA-TION UNDER A VEHICLE.

Blaisdell, G.L.

Blasseel, G.L. 36-1193 SNOW DEFORMATION, SNOW COMPRES-SION, LOADS (FORCES), VEHICLES, SNOW DENSITY, STRESSES, SNOW COMPACTION, TESTS.

TESTS.

In this report the deformation of snow under a vehicle is discussed. For snow with an initial density of less than 0.45 Mg/cu m, load transfer through shallow snow is shown to be attenuated by an interfacial boundary force. Evidence is presented that shows the existence of a density distribution in the deformed area. Results of a laboratory plate-sinkage test on sintered snow support this analysis. Maximum values obtained for the interfacial boundary force range from 1355 to 2670 N when the average density of the deformed area is about 0.5 Mg/cu m.

SR \$1-18 BOTTOM HEAT TRANSFER TO WATER BO-DIES IN WINTER.

O'Neill, K., et al, Sep. 1981, 8p., ADA-106-977. Ashton, G.D.

WATER TEMPERATURE, FREEZING POINTS, HEAT FLUX, HEAT TRANSFER, BOTTOM SEDIMENT, LIMNOLOGY, LAKES, PONDS, WINTER.

WINTER.

In many surface water bodics, water temperature closely follows ambient air temperature. This means that warmer water in winter absorbs best from below. The extent and pattern of winter heat gain is constrained by the fact that the water temperature does not fall below the freezing point. On the basis of a few simple assumptions, governing equations are solved here pertaining to heat flow in bottom sediments. The results are presented in general nondimensionalized curves. These allow estimation of water/sediment heat flux for any particular case, given truncation of the water temperature curve at the freezing point. The user must supply pertinent yearly air temperature mean and amplitude of variation, together with the thermal diffusivity for being a higher order finite element method which solves directly for temperature gradients and hence for heat flux. Thus the method provides particularly accurate flux values at high efficiency. The results illustrate in detail how winter water heat gain is less in cases where mean air temperatures are lower. temperatures are lower.

SR 81-19 MIZEX—A PROGRAM FOR MESOSCALE AIR-ICE-OCEAN INTERACTION; EXPERIMENTS IN ARCTIC MARGINAL ICE ZONES. 1. RE-SEARCH STRATEGY.

ICE AIR INTERFACE, ICE WATER INTERFACE, ICE EDGE, SEA ICE DISTRIBUTION, RESEARCH PROJECTS, CLIMATIC FACTORS, SEA
WATER, WATER TEMPERATURE.

This document describes the research strategy for a series of mesoscale studies of arctic marginal ice zones. The main goal of this program is to gain a better understanding of the processes occurring at the ice margin. These processes are relevant to climate, weather forecasting, petroleum exploration and production, marine transportation, naval operations, and commercial fisheries. In addition MIZEX will aid in determining what modifications to existing ice-ocean-atmospheric models are needed for better prediction near the

SR 81-20 MINE/COUNTERMINE PROBLEMS DURING WINTER WARFARE. FINAL REPORT OF A WORKSHOP.

EXPLOSIVES, COLD WEATHER PERFORM-ANCE, SNOW COVER EFFECT, BLASTING, FROZEN GROUND, RESEARCH PROJECTS.

FROZEN GROUND, RESEARCH PROJECTS.

The possibility of modern warfare being waged under cold weather conditions has raised questions about the effectiveness of conventional and new mine systems during the winter. A wortshop on mine-locuntermine winter warfare was held at the U.S. Army Cold Regions Research and Engineering Laborstory, 21-23 October 1980, to define problems related to cold climates. The designer, developer and user communities sent 22 representatives from 16 organizations outside of CRREL. Discussion papers were prepared by four groups, covering emplacement of mines, mane performance, detection of mines and neutralization of mines. The emphasis was on the unique problems of the winter environment tappears that the U.S. has the capability to conduct defensive warfare during the summer but is not adequately prepared for mine/countermine winter warfare. Test and research programs are called for to compensate for the prior lack programs are called for to compensate for the prior lack of consideration of the winter environment, to adequately winterize new mine/countermine systems, and to formulate appropriate doctrine for defensive winter warfare.

PERMAFROST, OIL SPILLS.

In 1974 personnel at the U.S. Army Cold Regions Research and Bagineering Laboratory (CRREL) began using an impulse radar system to profile accumulations of ice forms. Through field experience the system has been modified so that it can be effectively used as a profiling system, in a ground or airborne configuration, in certain high-noise environments. The system can penetrate fresh water and media with a high water content. For instance, frazil and brash ice accumulations with approximately 50% water have been profiled to a depth of 25 to 35 ft. As a result of the CRREL modifications, the system has found extensive and varied applications as a low-level remote sensing tool. Applications include profiling ice accumulations (including ice jams), river beds, sheet ice, permafrost, subsurface ice masses, river bank revenients through air-entrained water, snow covers, sea ice, icebergs, and peat bogs. Limited laboratory work has also shown that the impulse radar system may be able to detect oil and gas under sea ice. Selected applications and data are presented. Since it has been used mainly for research, the CRREL system needs further development to make it useful to operational units. Additional development of hardware and software is recommended.

SR 81-24 SITE INVESTIGATIONS AND SUBMARINE SOIL MECHANICS IN POLAR REGIONS.
Chamberlain, E.J., Oct. 1981, 18p., ADA-108 269, 44

SUBSEA PERMAFROST, SOIL MECHANICS, PROZEN GROUND MECHANICS, OCEAN BOTTOM, OFFSHORE DRILLING, OFFSHORE STRUCTURES, SITE SURVEYS, POLAR REGIONS, BEAUFORT SEA.

Placing oil exploration and production structures offshore in the Alaskan Beaufort Sea will require careful aits investigation and evaluation of submarine soil mechanics. Ico-bounded permafrost occurs widely under the Beaufort Sea floor. Its engineering properties are important to the design of offshore structures. Highly overconsolidated clays also occur widely and interfere with access to gravels for constructing artificial islands. Sites should be selected to avoid ice-rich permafrost. Laboratory tests may need to be conducted to determine the potential hazards of thaw consolidation and weakening. dation and weakening

IDENTIFYING AND DETERMINING HALO-CARBONS IN WATER USING GAS CHROMA-TOGRAPHY.

Leggett, D.C., Oct. 1981, 13p., ADA-108 345, 50 refs. 36-1749

WASTES, WATER CHEMISTRY, HYDROCAR-BONS, CHEMICAL ANALYSIS.

BONS, CHEMICAL ANALYSIS.
Since the discovery that chloroform and other haloforms are produced during water chlorination, methods have been needed for their routine analysis. This report describes application of the multiple equilibration headspace technique for the determination of halocarbons in water. This method has certain advantages over solvent extraction and direct injection techniques, including greater sensitivity because of the favorable gas/liquid distribution ratios. It is simpler and faster then purge and trap and resin sorption methods and gives more information about compound identity than single headspace analysis because gas/liquid distribution ratios are determined experimentally. The method is absolute, unlike solvent extraction, resin sorption, purge and trap, and conventional headspace analysis, which require standard additions to correct for incomplete recovery. The use of the technique to analyze chlorinated water samples for haloforms continued to form for 24 hours, even after destruction of chlorine residuals with thiosulfate. Maximum haloform concentrations were observed in undechlorinated samples only after a 48-hour aging period.

SYNOPTIC METEOROLOGY DURING THE SNOW-ONE FIELD EXPERIMENT.
Bilello, M.A., Nov. 1981, 55p., ADA-109 080, 3 refs.

SYNOPTIC METEOROLOGY, METEOROLOGI-CAL DATA, SNOWFALL, MEASURING IN-STRUMENTS, MAPPING.

STRUMENTS, MAPPING.

The daily atmospheric pressure systems and weather fronts that traversed the northeastern United States during the SNOW-ONE Field Experiment from 11 January through 20 February 1981 are summarized. This experiment is the first in a planned series of measurements to study the influence of atmospheric obscurants on electro-optical system performance. The analysis of the large-scale synoptic patterns that developed during the field test period constitutes a critical component of the research program. The weather during the measurement period included nine new daily high temperature records. January was one of the driest and February was one of the wettest ever observed. These conditions were caused in part by two high pressure cells and two major low pressure systems that crossed the region. One of these lows brought warm air and heavy rain to New England, and the other produced significant snowfall in northern Vermont.

LAND TREATMENT OF WASTEWATER.
Ryan, J.R., et al, Nov. 1981, 74p., ADA-108 636, Refs.
p.46-49. SITE SELECTION METHODOLOGY FOR THE

Loehr, R.C. 36-1853 WASTE DISPOSAL, WATER TREATMENT. LAND RECLAMATION, STIE ACCESSIBILITY.

A methodology is presented that covers facets of site selection from preliminary screening to field data acquisition for the preparation of a final deeign for a land treatment system. The basic assumption underlying the methodology is an approach to site selection in which the entire study area is investigated for potential sites while considering the whole spectrum of land treatment processes. Due to the extensive nature of such a study, several iterations are required to determine the most feasible site and land treatment alternatives. The methodology is presented in three parts. Level I defines the technical feasibility of implementing land treatment for a particular wastewater problem. The boundaries of the study area are defined and available land areas are rated for their suitability for land treatment based on topography, land use, hydrogeology and soil characteristics. A preliminary deeign for each suitable level I site candidates a prepared in the level II site analysis. The design is based on an evaluation of soil/waste interactions that considers evaluation of wate treatment alternatives and site candidates substitution of the land treatment alternatives and site candidates is developed in level II. The most cost-effective site candidates is then selected for intensive level III field investigations w i determine the design requirements of the land treatment system. MOBILITY BIBLIOGRAPHY.

Liston, N., comp, Nov. 1981, 313p., ADA-108 228. Hutt, M., comp, White, L., comp. 36-1491

TRAFFICABILITY, VEHICLES, BIBLIOGRA-PHIES, TRANSPORTATION, SNOW VEHICLES, AIR CUSHION VEHICLES, TRACKED VEHI-CLES, SNOW STRENGTH, SOIL STRENGTH.

This bibliography is an international compilation of literature relating to terrain vehicles, amphibious vehicles, anow vehicles, air cushion vehicles, tracked vehicles, wheeled vehicles, and off-road vehicles. It also covers the related subjects of

rolling resistance, traction, anow strength measurement, soil strength measurement, terrain analogs, vehicle models, and the overall topic of vehicle mobility. It is not comprehensive but begins at about 1970 and ends in 1980. The Buropean but begins at about 1970 and ends in 1980. The Euro coverage is lacking because much of this material is accessible by computerized literature searching, which the mechanism used for compiling this bibliography.

SR \$1.30 PREDICTING WHEELED VEHICLE MOTION RESISTANCE IN SHALLOW SNOW. Blaisdell, G.L., Dec. 1981, 18p., ADA-147 117, 14

refs.

59-572
RUBBER SNOW FRICTION, SNOW COMPACTION, VEHICLE WHEELS, SNOW DEPTH, SNOW COVER EFFECT, TRAFFICABILITY, VELOCITY, FORECASTING, MATHEMATICAL MODELS.

MODELS.

A vehicle traveling through snow is required to expend a greater amount of energy than is necessary when traveling on a rigid surface. Visually, this energy difference can be explained by the formation of a rut. Various attempts have been made in the past to equate the energy of compaction to vehicle motion resistance. However, many of the previous models use information gathered through the application of a vertical force (with a plate-sinkage device) to predict the horizontal motion resisting force. In an attempt to more accurately quantity the relationship between snow compaction and vehicle motion resistance, a vectorial analysis of compaction by a wheel is performed. A method for separating the compaction due to vehicle weight and forward thrust (horizontal propulsion) is suggested. Two methods of using this compaction force breakdown with field-generated data are proposed for the calculation of vehicle motion resistance in shallow snow.

SR 81-31 ROOF MOISTURE SURVEY: RESERVE CEN-TER GARAGE, GRENIER FIELD, MANCHES-TER, N.H.

JO-2-30 WATERPROOFING, MOISTURE, THERMAL INSULATION, WETTABILITY, BITUMENS, INFRARED BQUIPMENT, DRAINS, TEMPERATURE MEASUREMENT, MEASURING INSTRUMENTS.

ING INSTRUMENTS.

An insulated roof with a badly blistered bituminous builtup membrane was surveyed with a hand-held infrared camera to locate areas of wet insulation. Several thermal patterns were observed. Core samples were taken to determine moisture contents. Core samples verified that one thermal smomaly was caused by the increased thickness of bitumen. All other anomalies were caused by wet urethanepertite composite insulation. Some insulation boards contained much more moisture near the edges than at the center, but others were more uniformly wet. Dramatically different thermal patterns resulted. A few nuclear and capacita-ce readings, taken for comparison purposes, showed that extra bitumen adversely affects such sensing methods. Because of the amount of wet insulation and the condition of the membrane both should be removed. The new roofing system for this building should have internal drains and be provided with a sloped surface.

SR 81-32 AUTOMOTIVE COLD-START CARBON MONOXIDE EMISSIONS AND PREHEATER EVALUATION.

Coutts, H.J., Dec. 1981, 37p., ADA-112 170, 7 refs. 36-2751

ENGINE STARTERS, VEHICLES, COLD WEATHER OPERATION, AIR POLLUTION, TEMPERATURE EFFECTS.

TEMPERATURE EFFECTS.

Patrbanks and Anchorage, Alaska, experience high wintertime arbient levels of carbon monoxide (CO). Emissions from starting automobile engines in cold weather are thought to be a major source of CO. A quantitative procedure for determining startup CO was developed. The startup emissions were measured as a function of soak time at several low ambient temperatures. The performance of engine preheaters in reducing the startup CO at the verious soak times and temperatures was estimated. The data scatter was too great to draw any firm conclusions; however, the length of cold-soak time appeared to have a stronger effect on cold-start CO emissions than did soak temperatures (0 to -30C). Compared to no preheat, continuous preheat during an overnight cold soak can reduce the cold-start CO emissions by 20 to 90%.

SR 81-33 EFFECT OF SOIL TEMPERATURE AND PH ON NITRIFICATION KINETICS IN SOILS RE-CEIVING A LOW LEVEL OF AMMONIUM EN-

RICHMENT.
Parker, L.V., et al, Dec. 1981, 27p., ADA-112 171, Refs. p.17-20.
lakandar, I.K., Leggett, D.C.

36-2752

SOIL CHEMISTRY, SOIL TEMPERATURE, NUTRIENT CYCLE, WASTE TREATMENT, SOIL MICROBIOLOGY.

Two soil samples from an on-going field study of land application municipal wastewater were spiked with low levels of
sammonism to determine the effect of temperature on intrification kinetics. The concentrations of ammonium and nitriteplus-nitrate, and the number of autotrophic ammonium and
mitrite oxidizers were monitored periodically during the study.

There was a lag period prior to nitrite-plus-nitrate production
at all temperatures, and the length of this lag period was
temperature-dependent, with the longest period occurring at
the lowest temperature as expected. While nitriteplus-nitrate production appeared logarithmic, suggesting a
growing nitrifler population, the MPB counts of the nitrifiers
did not exhibit logarithmic growth. To study the effect
of soil pH on nitrification kinetics, soil samples from field
plots having the same soil type but different pHs (4.5, 5.5,
and 7.0) were spiked with low levels of ammonium and
the rate of nitrite-plus-nitrate production was greater at pH 5.5 than
at 4.5. Unexpectedly rapid disappearance of ammonium,
mitrite and nitrate, caused by immobilization, obscured the
expected effects of pH on the nitrification rate at the highest
pH.

SR 81-34 SEA ICE RUBBLE FORMATIONS IN THE BER-ING SEA AND NORTON SOUND, ALASKA. Kovacs, A., Dec. 1981, 23p., ADA-113 773, 22 refs.

36-2841
PRESSURE RIDGES, ICE PRESSURE, SEA ICE, OFFSHORE STRUCTURES, ICE LOADS, ICE FORMATION, ICE SURFACE, OFFSHORE DRILLING, GROUNDED ICE, FLOATING ICE. The occurrence of large, compact, grounded pressure ridge formations up to 15 m high in the coastal waters of Norton Sound and the Bering Sea is discussed. These formations periodically float free and drift about, gouging the seabed. Their mass makes them a severe threat to both floating and bottom-founded structures in these waters.

SR 82-01 OVERVIEW OF MODELS USED IN LAND TREATMENT OF WASTEWATER. Iskandar, I.K., Mar. 1982, 27p., ADA-114 403, Refs. p.22-27. 36-2910

Seilmann, P.V., Arcone, S.A.

PERMAPROST PERMAPROST PHYSICS, ELECTRICAL GROUNDING, ELECTRICAL RESISTIVITY, SA-LINE SOILS, GRAIN SIZE, ELECTRIC CHARGE, FROZEN GROUND PHYSICS, TESTS.

FROZEN GROUND PHYSICS, TESTS.

This study shows that resistance to ground of a simple vertical electrode in frozen fine-grained soil can be lowered significantly by placing it in a hole backfilled with a conductive soil-salt mixture. These tests were performed near Fairbanks, Alaska, in perennially frozen silt. Three electrodes were installed in holes created by detonating standard military shaped charges placed at the ground surface. The backfill contained varying amounts of salt. Measurement of resistance to ground of each electrode was made seasonally. The resistance to ground was lowered by an order of magnitude by the addition of a water-saturated salt-soil backfill. Improvement persisted six months after the backfill was placed and allowed to freeze. The degree of improvement provided by this technique will be a function of grain size and permeability of the surrounding soil.

SR \$2-14 EVALUATION OF A SIMPLE MODEL FOR PREDICTING PHOSPHORUS REMOVAL BY SOILS DURING LAND TREATMENT OF WAS-

TEWATER. Ryden, J.C., et al, June 1982, 12p., ADA-117 848, 35

36-4092

WASTE TREATMENT, WATER TREATMENT, SOIL CHEMISTRY, FORECASTING, LANI RECLAMATION, MATHEMATICAL MODELS.

RECLAMATION, MATHEMATICAL MODELS. This report evaluates a simple P balance model to predict site longevity with respect to P removal during land treatment of wastewater. The model is based on measured inputs and outputs of P at the treatment site and on an estimate of the P storage capacity of the soil profile. Sorption P by three soils used for land treatment conformed to the P sorption model based on a generalized isotherm. Laboratory sorption tests were used to predict P storage capacity of the soil profiles at a solution P concentration equivalent to that in the effluent applied to the soil. For two soil profiles the P balance model predicted site longevities of approximately 50 and 210 years. The existing depth of P enrichment in these profiles predicted from the model agreed closely with measurements of P enrichment based on amounts of NaOH-extractable P and on measured soil solution P concentrations.

SR 82-15 LIMNOLOGICAL INVESTIGATIONS: LAKE **EOOCANUSA, MONTANA. PART 4: FACTORS CONTROLLING PRIMARY PRODUCTIVITY.** Woods, P.F., et al, June 1982, 106p., ADA-119 328, Refs. p.54-63.

Falter, C.M.

BIOMASS, RESERVOIRS, LIMNOLOGY, DAMS, PHOTOSYNTHESIS, LAKE WATER, WATER

Postimpoundment loadings of total nitrogen and total phos-phorus delivered to Lake Koccanusa by the principal inflowing stream, the Koctensi River, were predicted to be large enough to cause eutrophication of the lake; however, measured annual to cause europhication of the lake; however, measured annual primary productivity for 1972 through 1075 was relatively low, and characteristic of oligotrophic values because phytoplankton photosynthesis was suppressed by physical limnological factors. The predominant flood-control function of the reservoir necessitates substantial reductions in volume during the autumn and winter. These large-scale water movements weakened the thermal structure of the reservoir.

Concentrations of orthophosphate, IR1 and IR2 obscurants were measured in surface snow samples after a winter test of white phosphorus (WP) smoke and the two infrared acreesers. Sample concentrations of IR1 and IR2 decreased exponentially downwind from the smoke release point. Orthophosphate concentrations were all lower than the analytical detection limit of 0.15 mg/L. Quantities of smoke released pose no hazard to the public or environment. Snow was found to provide a clean non-contaminating surface upon which to collect the deposited aerosol. SR 82-20

LIMNOLOGY, LAKE WATER, DAMS, WATER POLLUTION, RESERVOIRS, NUTRIENT CYCLE, UNITED STATES—MONTANA— KOOCANUSA, LAKE.

KOCCANUSA, LAKE.

This report documents the effects of the construction of Libby Dan upon the water quality of the United States portion of the Kootenai River during the pre-impoundment phase of a long-term water quality study. Water quality problems during dam construction appeared to be restricted to short-term increases in suspended sediment and turbidity which suppressed the aquatic insect population in the river downstream. Abnormally high background concentrations and abrupt chemical changes in water quality during the course of the study were attributed to industrial discharges from a fertilizer plant and mining operation located on an upstream tributary to the river. Nutrient loadings of nitrogen and phosphorus were found to be of sufficient magnitude to predict the development of eutrophic conditions following impoundment suggesting that efforts in controlling nutrient point sources be continued.

SR 82-22 SM 52-22 SUPPRESSION OF ICE FOG FROM THE FORT WAINWRIGHT, ALASKA, COOLING POND. Walker, K.E., et al, Oct. 1982, 34p., ADA-123 069, 28

Brunner, W. 39-1729

39-1729
ICE FOG, VISIBILITY, COUNTERMEASURES, PONDS, COOLING SYSTEMS, AIR TEMPERATURE, VEHICLES, ACCIDENTS.
Ice fog near the Pt. Wainwright cooling pond creates a visibility hazard. Observations show a substantial reduction in visibility along both private and public roadways in the path of the cooling pond's ice fog plume. This reduction in visibility increases as the ambient air temperature decreases. Visibility was less than 215 m (700 ft) on the Richardson Highway on the average of 8 days for each of the 3 data years. Data collected during the winters of 1979-80, 1980-

81 and 1981-82 statistically show that use of a monomolecular film evaporation suppressant, hexadecanol, on the pond to reduce ice fog is ineffective. There is an immediate need for a driver warning system when visibility is affected by the ice fog.

WASTE TREATMENT, WATER TREATMENT, CHEMISTRY, NUTRIENT CYCLE, PLANT PHYSIOLOGY, WATER RETENTION.

PHYSIOLOGY, WATER RETENTION.

An experiment was conducted to determine the feasibility of using several plant species in a pilot-scale nutrient film technique (NFT) installation to further treat primary-treated effluent. The reduction of biochemical oxygen demand, total suspended solids, and nitrogen and phosphorus concentrations by the NFT is discussed. Tracer studies aboved that the hydraulic retention time of the wastewater in the NFT trays was inversely related to the wastewater application rate, and that for a given flow, plants with fine root systems (such as reed canarygrass) had a much longer detention time than plants with coarse tuberous rhizomes (such as cattails). The BOD reduction could be described using the plug-flow reactor model with first-order kinetics.

SR 22-28 PHYSICAL PROPERTIES OF THE ICE COVER OF THE GREENLAND SEA.

PAST ICE, PACK ICE, GREENLAND SEA.

There is very little information available on the physical properties of the ice cover of the Greenland Sea. This paper reviews what is known about the different types of ice that are believed to occur in this area. It also discusses how the internal structure and composition of these ice masses may differ from those of the more extensively studied ice of the Beaufort Sea and identifies gaps in the present knowledge of the properties of such ice masses (regardless of places of origin). Finally a strategy is outlined for efficiently studying the properties of the ice in the Greenland Sea by combining structural and compositional characterization with limited property determinations.

BASELINE WATER QUALITY MEASURE-MENTS AT SIX CORPS OF ENGINEERS RESERVOIRS, SUMMER 1981.

RESERVOIRS, WATER CHEMISTRY, WATER POLLUTION, CHEMICAL ANALYSIS, WATER TEMPERATURE, SUSPENDED SEDIMENTS.

TEMPERATURE, SUSPENDED SEDIMENTS.

Water quality information was collected at six reservoirs of the New England Division, U.S. Army Corps of Engineers, during the summer and fall of 1981. The reservoirs tested included Ball Mountain in Jamaica, Vermont, Everett and Hopkinton-Elm Brook in Hopkinton, New Hampshire, North Hartland in North Hartland, Vermont, Stoughton Pond and North Springfield, Vermont, and Townshend, Vermont. Field measurements includate the contract of the contraction of the contractio shend in Townshend, Vermont. Field measurements included temperature, pH, conductivity, dissolved oxygen, depth, and the point of visual extinction. Laboratory analyses included determination of total suspended matter, turbidity, alkalinity, ammonium, nitrate, orthophosphate, total phosphorus, total nitrogen, total organic carbon, heavy metala (Zn, Pb, Cd and Cr), fecal coliforms, and chlorophyll a

SR 82-31 RESERVOIR BANK EROSION CAUSED AND INFLUENCED BY ICE COVER.
Gatto, L.W., Dec. 1982, 26p., ADA-124 508, Refs.

p.20-26. 38-4040

BANKS (WATERWAYS), SOIL EROSION, ICE EROSION, RESERVOIRS, ICE COVER EFFECT, EROSION, WATER LEVEL, BEACHES.

EROSION, WATER LEVEL, BEACHES.
The purpose of this study was to evaluate the importance of reservoir bank erosion caused by an ice cover. The evaluation is based on a literature review and on inferences made from field observations and experience. Very little is known about the amount of reservoir bank erosion caused by the actions of an ice cover, although considerable information is available on the processes of ice-related erosion along the shorelines or beaches of oceans, rivers or lakes. The importance of ice-related erosion along a reservoir bank seems to be determined primarily by water level. If the reservoir water level is high enough for ice to act directly on the bank face, the amount of erosion caused by ice could be substantial. If the water level is below the bank, ice would have no direct effect on it. However, ice could indirectly increave bank instability by disrupting and eroding nearshore and beach zones, which could lead to bank erosion.

SR 82-32 DEVELOPING A WATER WELL FOR THE ICE BACKFILLING OF DYE-2.

Rand, J.H., Dec. 1982, 19p., ADA-125 503, 11 refs. 39-1730

WATER SUPPLY, ICE MELTING, WELLS, LOG-ISTICS, GREENLAND.

One proposal to extend the useful life of DEW Line Ice Cap Station DYE-2 is to backfill the lower 50 feet of the truss enclosure with ice. This report discusses a method by which 2.8 million gallons of water would be collected and stored by melting ice. Also included is a description of required components, their costs and the logistical requirements to establish such a system.

SR 82-33

INFRARED INSPECTION OF NEW ROOFS. Korhonen, C., Dec. 1982, 14p., ADA-125 502, 9 refs.

PHOTOGRAPHY, THERMAL INSULATION, BUILDINGS.

BUILDINGS.

The feasibility of using infrared cameras to detect wet insulation during the typical 1-year warranty period for new Army roofs was studie. Both the ability to gain moisture and the manner of westing of insulations were of major concern. Although some insulations take on moisture much slower that others, 8 to 10 months usually is ample time for most insulations to absorb enough moisture to be detectable by an infrared camera. However, the early signs of this moisture as seen with the infrared camera differ with insulation type. Basically, boards of slower-wetting cullular plastic insulations initially wet at their perimeters, whereas highly absorbent fibrous insulations tend to wet more or less uniformly. An infrared camera is well suited for finding the typically small and sometimes irregularly ahaped wet areas on a new roof. A specification incorporating this technology should be now tested. now tested.

WASTE TREATMENT, WATER TREATMENT, LAND RECLAMATION, DESIGN, MODELS, NUTRIENT CYCLE, AGRICULTURE.

NUTRIENT CYCLE, AGRICULTURE.

A procedure to evaluate design and operating options for slow-rate land treatment systems is demonstrated. The nonlinear optimization model LTMOD is used to generate optimal monthly operating regimes (effluent application patterns) and to define optimal design configurations (combinations of storage capacity and irrigation area). The model is applied to a hypothetical slow-rate land treatment system in a cool, humid area with a forage crop, where the operation and design of the system is constrained by the potential for nitrogen renovation in the storage facility and in the soil-crop system. The cost properties over the range of optimal design alternatives are examined to deduce some general cost characteristics of slow-rate systems ranging from 0.5 to 10 mgd.

WASTE TREATMENT, WATER TREATMENT, SANITARY ENGINEERING, LAND RECLAMA-TION, BIBLIOGRAPHIES.

IIUN, BIBLIUGRAPHIES.
This bibliography contains publications of research funded in whole or in part by the Corps of Engineers Land Treatment Research Program, conducted from January 1972 to May 1982.
The program was officially complete in October 1980. Six types of publications are included: 1) publications in open literature (which may include papers in journals, chapters in books and books), 2) technical reports, 3) engineer technical letters, 4) draft translations (mainly from Russian), 5) theses and dissertations (M.S., Ph.D.), and 6) presentations at scientific conferences.

SYNOPTIC METEOROLOGY DURING THE SNOW-ONE-A FIELD EXPERIMENT.
Biello, M.A., May 1983, 80p., ADA-134 888, 8 refs.

38-885

38-865 SNOWFALL, STORMS, FREEZING, SYNOPTIC METEOROLOGY, PRECIPITATION METEOROLOGY, (METEOROLOGY). METEOROLOGICAL

DATA.

The daily atmospheric systems and weather fronts that traversed the northeastern United States during the SNOW-ONE-A Field Experiment from 30 November to 20 December 1981 and from 3 January to 10 February 1982 are summarized. This experiment is the second of a series of winter measurements of the influence of atmospheric obscurants on electropotical system performance. The analysis of the large-scale synoptic weather patterns that developed during the field test period constitutes a critical component of the research program. Precipitation in northern Vermont during SNOW-ONE-A was near normal for the region. Numerous separate snowfall events, including some with substantial amounts of snow, were recorded during the experiment period. Almost all of the storms that produced more than 6 cm of snow resulted from coastal cyclogenesis or developing waves that deepened as they moved north on northeastward along the Atlantic coastline. The majority of the other events with lighter amounts of freezing precipitation were caused by leas intense storm systems, troughs, or fronts that traversed the region from the west or northwest and often moved quite rapidly.

EFFECT OF VESSEL SIZE ON SHORELINE AND SHORE STRUCTURE DAMAGE ALONG THE GREAT LAKES CONNECTING CHAN-

Wuebben, J.L., May 1983, 62p., ADA-134 887, 13 refs. 40-4677

SHORES, CHANNELS (WATERWAYS), ICE LOADS, SHIPS, STRUCTURES, DAMAGE, VELOCITY, GREAT LAKES.

VELOCITY, GREAT LAKES.
In conjunction with the Great Lakes connecting channels and harbors study, this report examines the potential damage to the shore and shore structures due to an increase in vessel size. The areas considered in this report are the United States shorelines along the St. Marys, St. Clair and Detroit rivers. The potential for shoreline or shore structure damage due to an increase in vessel size was reviewed on both a conceptual and site-specific basis. Ship-induced waves were ruled out as a damage mechanism since the analysis showed that the contemplated increases in vessel size would not significantly affect wave heights in the nearshore zone. Propeller wash was discounted for similar reasons. Ship-induced drawndown was determined to be the major potential damage mechanism. While larger ships potentially produce more damage, this potential is significant only in severely restricted channel sections for the size increase considered here. By far the most significant factor in ship-related damage potential is vessel speed. In almost all areas the effect of an increase in vessel size could be eliminated by a reduction in vessel speed of 1-2 mph.

SR 83-12 -A PROGRAM FOR MESOSCALE AIR-ICE-OCEAN INTERACTION EXPERIMENTS IN ARCTIC MARGINAL ICE ZONES. 2. A SCIENCE PLAN FOR A SUMMER MARGINAL ICE ZONE EXPERIMENT IN THE F.AM STRAIT/GREENLAND SEA: 1984.

METEOROLOGICAL DATA, SEA ICE, ICE TEM-PERATURE, WIND VELOCITY, AIR TEMPERA-TURE, HUMIDITY, SOLAR RADIATION, AN-TARCTICA—WEDDELL SEA.

TARCTICA—WEDDELL SEA.

This report summarizes a comprehensive set of surface-level meteorological data collected on the Mikhail Somov over sea ice in the southern ocean during the U.S.-U.S.S.R. Weddell Polynya Expedition in October and November of 1981. The data assembled here comprise three distinct sets of measurements: the standard meteorological observations at 3-hour intervals for 41 consecutive days, radiation and ice-surface temperature measurements every hour for 23 days while the Somov was within the Antarctic ice pack, and 23 sets of atmospheric surface-layer profiles of velocity, temperature and humidity for various sea-ice conditions. (Auth.)

SR 83-15 SHORELINE EROSION AND SHORE STRUC-TURE DAMAGE ON THE ST. MARYS RIVER. Wuebben, J.L., May 1983, 36p., ADA-134 863, 4 refs. 38-886

SHORELINE MODIFICATION, SHORE ERO-SION, FAST ICE, SEDIMENT TRANSPORT, STRUCTURES, DAMAGE, ICE NAVIGATION, ICE FLOES, PIERS.

ICE FLOES, PIERS.
From 1961 to 1970 navigation on the St. Marys River closed for the winter from mid-December to mid-April. Subsequent extension of the navigation season to include the winter months resulted in complaints of shoreline and dock damage along the navigation channels. Studies were initiated to examine the potential for navigation-caused damage, but information on damage during a navigation-free winter was lacking. Since limited navigation was planned during the 1979-80 winter, the St. Marys River System could be examined under relatively undisturbed conditions. The report examines potential navigation-related damage mechanisms and presents data from the closed navigation season. The results are compared with information collected during previous periods with winter navigation.

SN 83-16 SNOW-ONE-B DATA REPORT. Bates, R.E., ed, June 1983, 284p., ADB-088 224, Refs. passim. For individual papers see 39-1952 through 39-1961. For SNOW-ONE-A—preliminary data re-port see 37-1094 (SR 82-8). Bowen, S.L., ed. 39-1951

17, ELECTROMAGNETIC PROPERTIES, OPTI-CAL PROPERTIES, TRANSMISSION.

This is the third in a series of data reports on the SNOW field experiments of the U.S. Army Corps of Engineers winter Battlefield Obscuration Research Program. It contains data obtained by the U.S. Army Cold Regions Research and Engineering Laboratory and other agencies during the SNOW-ONE-B field experiment at Camp Grayling, Michigan, between 30 November and 17 December 1982. Included are data on meteorology, atmospheric turbulence, visible and IR transmission, snow characterization, millimeter wavelength radar propagation, transmittance through falling and blowing radar propagation, transmittance through falling and blowing snow, the lidar system, the SMART system, and preliminary smoke trials with snow as a contrast background.

FROZEN GROUND STRENGTH, LOADS
(FORCES), UNFROZEN WATER CONTENT,
SOIL WATER, TEMPERATURE MEASUREMENT, NUCLEAR MAGNETIC RESONANCE, THERMODYNAMICS.

THERMODYNAMICS.

Frozen samples of a Manchester silt having various total water contents were subjected to several surcharge loads, and the unfrozen water content was measured with NMR as the temperature was gradually raised. The surcharge pressure had a greater effect on the unfrozen water content than had been predicted using the Clausius-Clapeyron equation. This effect was explained by considering the loaded samples as nonequilibrium systems in which the surcharge pressures were concentrated in the ice phase.

SR 83-19

PREDICTING LAKE ICE DECAY.

Ashton, G.D., June 1983, 4p., ADA-132 012, 4 refs.

LAKE ICE, ICE DETERIORATION, HEAT TRANSFER, FORECASTING, DEGREE DAYS, ANALYSIS (MATHEMATICS).

A nine-year record of the lake ice decay pattern of Post Pond in Lyme, New Hampshire, is analyzed using a simple algorithm. Quite good correlations between decay rates and thawing degree-days are obtained using heat transfer coefficients on the order of 15-20 W/sq m/deg C.

REPORTS OF THE U.S.-U.S.S.R. WEDDELL POLYNYA EXPEDITION, OCTOBER-NOVEM-BER 1981, VOLUME 5, SEA ICE OBSERVA-TIONS.

Ackley, S.F., et al, Jan. 1983, 6p. + 59p., ADA-130 140, 4 refs. Smith, S.J.

39-380

ICE DISTRIBUTION, POLYNYAS, ICE SEA ICE DISCONDITIONS.

CONDITIONS.

Sea ice conditions are presented in several formats. These include an ice conditions map prepared by the ship's meteorological crew, a narrative ice log supplemented by photographs taken by one of the authors, and daily satellite photographs. These are presented in a format compiling each day's conditions on one or two pages. These observations are being correlated with other satellite-based estimates of ice conditions, and with other oceanographic and meteorological measurements made during the expedition. (Auth.)

SNOW COVER AND METEOROLOGY AT AL-LAGASH, MAINE, 1977-1980. Bates, R., June 1983, 49p., ADA-132 013, 4 refs.

38-472

38-472 SNOW COVER DISTRIBUTION, SNOW SUR-VEYS, SNOW WATER EQUIVALENT, PRECIPI-TATION (METEOROLOGY), WEATHER STA-TIONS, METEOROLOGICAL DATA, UNITED

TIONS, METEOROLOGICAL DATA, UNITED STATES—MAINE—ALLAGASH.

A complete meteorological field station and a snow survey network were set up in the Allagash River Watershed to record baseline conditions prior to construction of the proposed Dickey-Lincoln Dam in the upper St. John River Basin in Allagash, Maine. Nearly three years of daily data (Oct 1977-May 1980) are summarized and compared to long-term climatic conditions for nearby National Weather Service stations. Air temperature values for Allagash are similar to those for the two nearest meteorological stations; water equivalent precipitation amounts and snowfall totals water equivalent precipitation amounts and anowall totals in the Allagash basin are inconsistent with those for nearby meteorological stations.

SR 83-21 EXAMINATION OF A BLISTERED BUILT-UP ROOF: O'NEILL BUILDING, HANSCOM AIR FORCE BASE.

Korhonen, C., et al, June 1983, 12p., ADA-133 042,

Greatorex. A

38-123

ROOFS, DEFORMATION, COLD WEATHER TESTS, MOISTURE, INFRARED SPECTROS-COPY.

COPY.

Bisters are a common defect in built-up roofs. In January 1983 we examined a recently constructed built-up roof at Hanscom Air Force Base in Bedford, Massachusetts, to determine the cause of its blisters. We used an infrared scanner, took ten core samples, conducted visual examinations, and cut open three bisters. Dur findings show that the membrane is essentially watertight and that the blisters were caused by voids that were built into the roof during construction. Poor workmanship and cold weather are the likely causes of the voids. With proper maintenance reasonable performance can be achieved from this imperfect roof.

SR 83-22 ESTIMATING TRANSIENT HEAT FLOWS AND MEASURING SURFACE TEMPERATURES OF A BUILT-UP ROOF.

Korhonen, C., July 1983, 20p., ADA-133 043, 4 refs. 38-541

HEAT TRANSFER, SURFACE TEMPERATURE, ROOFS, INFRARED EQUIPMENT, THERMAL INSULÁTION.

Transient heat flow through a multilayered building compone can be estimated using the transfer function method present in the ASHRAE (1977) Handbook of Fundamentals. So in the ASHRAE (1977) Hasobook of Fundamentals. Solitative temperature is one parameter recommended for use in this method, but surface temperatures were shown to be a reasonable substitute. Although the magnitude of the heat flow as calculated with the transfer function appears to be reasonable, more testing should be carried out to determine its accuracy. An infrared camera can measure roof surface temperatures fairly accurately; the most accurate measurements were made at night.

SP 83-23 AEROSTAT ICING PROBLEMS.

Hanamoto, B., Aug. 1983, 29p., ADA-133 403. 39-874

BALLOONS, ICING, PROTECTIVE COATINGS, ICE PREVENTION, COATINGS.

This report describes laboratory tests to determine the effectiveness of a copolymer coating on a balloon to minimize ice build-up problems when operating in sleet, freezing rain or other ice-forming conditions. Methods for descring the surface after an ice cover forms are also described. A small-scale balloon was used for the laboratory tests. A full-scale prototype was also partially coated with the copolym-er to test its effectiveness as an icing control measure

SR 83-24 CURRENT PROCEDURES FOR FORECASTING

Tucker, W.B., Aug. 1983, 31p., ADA-136 152, 23 refs. 38-2437

AIRCRAFT ICE FORECASTING. ICING. WEATHER FORECASTING, METEOROLOGI-CAL FACTORS.

The responsibilities for aircraft icing forecasts in the U.S. lie with the National Weather Service (NWS) for civilian operations and the U.S. Air Forece Air Weather Service (AWS) and Naval Weather Service for military operations. Forecasting technology is based upon empirical rules and techniques that were developed in the 1950s. The AWS is the only forecasting assency which issues explicit numerical techniques that were developed in the 1950s. The AWS is the only forecasting agency which issues explicit numerical icing products to aid the forecaster. These products are also based upon the application of techniques developed long ago. The NWS has no rigorous guidelines for developing icing forecasts, thus individual forecasters adopt their own preferred methods. The tendency is generally to "overforecast," that is, to forecast too large an area of icing for too long a time. A major shortcoming in the ability to produce more accurate forecasts is that atmospheric parameters critical to icing are not routinely observed.

SR 83-25 UNDERSTANDING THE ARCTIC SEA FLOOR

FOR ENGINEERING PURPOSES.
National Research Council. Committee on Arctic Seafloor Engineering, 1982, Washington, D.C., National Academy Press, 1982, 141p., ADA-119 773, Refs. p.115-141.

METEOROLOGICAL INSTRUMENTS, MEATOTAL INSTRUMENTS, SHIPS, BOOMS (EQUIPMENT), ANTARCTICA.

(EQUIPMENT), ANTARCTICA.

We have developed a simple boom for use in measuring meteorological variables from a ship. The main structural member of the boom, a triangular communications tower with rollers attached along its bottom side, is deployed horizontally from a long, flat deck, such as a helicopter deck, and will support a 100-tg payload at its outboard end. The boom is easy to deploy, requires minimal ship modifications, and provides ready access to the instruments mounted on it. And because it is designed for use with the ship crosswind, oceanographic work can go on at the same time as the air-sea interaction measurements. We describe our use of the boom on the Mikhail Somov during a cruise into antarctic sea ice and present some representative measurements and ewith instruments mounted on it. Theory, experiment, and our data all imply that instruments deployed windward from a rear helicopter deck can reach air undisturbed by the ship. Such an instrument site has clear advantages over the more customary mast, bow, or buoy locations. (Auth.) (Auth.)

DATA PROCESSING, ANALYSIS (MATHEMATICS), COMPUTER PROGRAMS, THEORIES.

ICS), COMPUTER PROGRAMS, THEORIES.

A BASIC algorithm has been developed that is capable of fitting a user-defined regression equation to a set of data. This best-fit-curve algorithm is unique in that it allows multiple variables and multiple forms (exponential, trigonometric, logarithmic, etc.) to be present in a single regression equation. The least-equares regression performed determines the constants for each of the regression equation terms to provide a best-fit curve.

Other programs within the algorithm set allow for data entry, editing and printout, and plotting of the raw data and their best-fit regression curve.

MICHIGAN—SAGINAW RIVER.

A May 1977 Landast-2 scene that covered approximately 85% of the Saginaw River Basin was classified into five land cover categories (urban, agriculture, forest, freshwater wetlands and open water) using a closest centroid classifier. The Landast digital data were geometrically corrected to conform to a UTM (Universal Transverse Mercator) grid before classification. The 1.1-acre Landast land cover classification data base was converted to 40-acre grid cells (simb-y-six blocks of Landast pixels) using an aggregation scheme and was integrated into the Detroit District's existing grid cell data base. A regression relationship between unit hydrograph parameters and the Landast land cover classification was developed. The results indicated that the Landast land cover data were suitable for the Corps of Engineers 2 land cover data were suitable for the Corps of Engineers hydrologic model.

SR 84-02 ICE OBSERVATION PROGRAM ON THE SEMISUBMERSIBLE DRILLING VESSEL VESSEL SEDCO 708.

Minsk, L.D., Feb. 1984, 14p., ADA-139 992, 5 refs. 38-4045

SHIP ICING, ICE CONDITIONS, ICE FORMATION, ICE PREVENTION, PROTECTIVE COATINGS, OFFSHORE DRILLING, SHIPS, SEASPRAY.

A semisubmersible drilling vessel (SEDCO 708) was equipped with ice detectors and ice socretion measurement devices, and observations were conducted while it drilled an exploratory well on the North Aleutian Shelf.

One significant storm

occurred 3-8 January 1983, which resulted in light spray ice accretion, estimated at 30 tons and a maximum thickness of 5 in. on understructure diagonal trusses. Only minor icing (less than 1 in.) occurred on the windward main columns (30 ft diameter). Comparison with the 1979 Ocean Bounty icing event suggests that wind speed is the significant parameter influencing icing severity, and that light icing will occur at average speeds around 30 knots and heavy icing around 88 knots, with undefined severity within the range. Four icephobic coatings were exposed on test panels; one was effective.

FBCIS, CRACKING (FRACTURING).

The United States Air Force Roof Condition Index Survey (RCI) procedure was studied and used on the roofs of Fort Greely, Alaska. Approximately 93 roof sections were inspected using this procedure. The results will be used in a comparison study between this method and the Army's method of infrared roof surveys and core samples. This report details the RCI method, discusses various aspects of the procedure and presents the results of the Fort Greely

SR 84-04

ASSESSMENT OF ICE ACCRETION ON OFF-SHORE STRUCTURES.

Minsk, L.D., Apr. 1984, 12p., ADA-141 996, 19 refs. 38-4047

ICE ACCRETION, OFFSHORE STRUCTURES, SEA SPRAY, SHIP ICING, OFFSHORE DRILL-ING.

ING.

The literature on sea spray (superstructure) icing is almost entirely based on observations on moving ships. However, icing on stationary offshore platforms with their fixed vertical columns will differ significantly from ship icing, which is influenced by ship movement and wind and wave directions. An observation program on offshore drilling vessels is proposed, using 1-in.-diam x 8-in.-long cylinders in arrays as a standard measuring technique for spray icing. Atmospheric icing may be a source of ice accretion on derricks in some locations, and the best commercial device currently available for measuring it is the Rosemount detector. Improved devices for both spray and atmospheric ice accretion measurements should be developed. Icephobic coatings have the potential for reducing ice accretion, and testing of candidate materials should be undertaken. Well-documented icing reports by all types of ships or platforms should be made and collected at a central clearinghouse.

SEWAGE TREATMENT, SANITARY ENGINEERING, SLUDGES, FREEZE THAW CYCLES, MODELS, POLAR REGIONS.

MODELS, POLAR REGIONS.
Accumulated solids associated with the operation of aerated and facultative lagoons in cold climates were investigated to determine 1) the rate and extent of solids accumulation. 2) the characteristics of the accumulated solids, 3) the potential for in situ stabilization of the accumulated solids, and 4) the effect of lime treatment upon the pathogenic population and subsequent solids drying on sand and soil beds. Accumulated sludges from the Logan and Corinne, Utah, facultative lagoons and the Palmer and Galena, Alasks, partial mix aerated lagoons were studied. The rates of accumulation, determined by in situ measurement of the sludge layer in each lagoon, were found to vary with lagoon type and specific operational and environmental conditions.

SR 84-09 PROCEDURE FOR CALCULATING GROUND-WATER FLOW LINES.

Daly, C.J., Apr. 1984, 42p., ADA-141 947, 4 refs.

GROUND WATER, WATER FLOW, FLUID FLOW, COMPUTER PROGRAMS, MATHEMATICAL MODELS, WATER TABLE, VELOCI-TY.

A methodology for the calculation of flow lines in steady or unsteady two-dimensional velocity fields is described. Although the principal application is intended to be determined fluid particle trajectories in groundwater flow, components of the methodology are relevant to more general problems of fluid flow. Two alternative numerical procedures form the core of the methodology. Each employs the method of characteristics to solve for the advection of fluid particles. The first uses an efficient, fourth-order Rungo-Kutta, predictorcorrector algorithm based upon a constant time step. corrector algorithm based upon a constant time step. The second use a fifth-order Runge-Kutta algorithm incorporating an embedded fourth-order result. This latter alternative includes automatic time-step modification and guarantees a prescribed level of accuracy. Several utility routines are provided in support of the method of characteristics.

WASTE TREATMENT, WATER TREATMENT, SEEPAGE, FLOW RATE, SOILS, LAND RECLAMATION, SITE SURVEYS, TESTS.

A 6-ft-diam flooding infiltration test was conducted at a proposed wastewater land treatment site near Chapel Hill, North Carolina. The saturated infiltration rate of the soil was 0.13 in./hr, and the reservation rate of the saturated

oil was equivalent to 1.35 in. of water after six days. A conservative wastewater application rate at this site would be between 1 and 2 in./wk.

DETERIORATED CONCRETE PANELS ON BUILDINGS AT SONDRESTROM, GREEN-

Korhonen, C., May 1984, 11p., ADA-142 595, 4 refs. 38-4054

CONCRETE STRUCTURES, CONCRETE STRENGTH, BUILDINGS, REINFORCED CONCRETES, DAMAGE, MOISTURE TRANSPORT, THERMAL EFFECTS, FREEZE THAW CYCLES, GREENLAND.

On July 22 1983 a dozen reinforced concrete buildings, built in 1954 at Sondrestrom Air Base in Greenland, were built in 1954 at Sondrestrom Air Base in Greenland, were examined to determine why their concrete wall panels were cracked, spalled and rust stained. The investigation determined that structural and thermal movements caused most of this deterioration. Very little freeze-thaw deterioration was evident on the outside, but the most serious problem was that of frost damage within the wall cavities fed by moisture from the inside of each building. The visible surface defects can be repaired with breathable patching materials, but to achieve long-term success and to minimize wall-cavity frost damage, vapor migration through the walls must be properly controlled.

PERFORMANCE OF THE ALLEGHENY RIVER ICE CONTROL STRUCTURE, 1983.

Deck, D.S., et al, May 1984, 15p., ADA-144 094, 3 refs.

39-381

ICE CONTROL, ICE BOOMS, RIVER ICE, FRA-ZIL ICE, ICE BREAKUP, ICE JAMS, UNITED STATES—PENNSYLVANIA—ALLEGHENY

RIVER.

Oil City, Pennsylvania, is at the confluence of the Allegheny River and Oil Creek. The business district is located in the flood plain, and ice jam flooding has been a persistent problem. A floating ice control structure was installed on the Allegheny River prior to the 1983 ice season. The structure was a steel pontoon ice boom located upstream of Oil City and was used to encourage early formation of an ice cover at this location. This would suppress prolonged frazil ice generation, which in the past led to a massive freezeup jam downstream. This accumulation would prevent the discharge of ice from Oil Creek during breakup, when ice jam flooding would occur. The performance of the structure during its first year is documented here. Oil City escaped ice jam flooding during the winter of 1983. here. of 1983.

ON-SITE UTILITY SERVICES FOR REMOTE MILITARY FACILITIES IN THE COLD RE-**GIONS**

Reed, S.C., et al, May 1984, 66p., ADA-142 596, 20

Ryan, W.L., Cameron, J.J., Bouzoun, J.R. 38-4055

MILITARY FACILITIES, WASTE TREATMENT, WASTE DISPOSAL, WATER TREATMENT, WATER SUPPLY, UTILITIES, COLD WEATHER PERFORMANCE, THERMAL EFFECTS, DE-SIGN CRITERIA.

Utility services (water, sewer, solid wastes) for small, remote military facilities in cold regions require special considerations. This report presents concepts and criteria for the planning and preliminary design of internal and external utility systems. Also included are some thermal aspects for design of these water and wastewater systems.

CALCULATING BOREHOLE GEOMETRY FROM STANDARD MEASUREMENTS OF BOREHOLE INCLINOMETRY.

Alley, R.B. 39-475

BOREHOLES, ICE DRILLS, DRILLING, MEAS-UREMENT, GREENLAND.

This report is an extension of the authors' earlier registance This report is an extension of the authors' earlier resistance-tronground experiments. Here they supply additional infor-mation on the influence of salt-treated backfills around ground-ing electrodes for reducing resistance to ground. The results are based on observations made over several seasons of freezing and thawing at sites selected for their variations in grain size, ice content, and ground temperature. More than 20 test electrodes were monitored at two sit sites and one alluvial site. The diameter of the backfilled zones, the salt content, and the backfill material were varied for the electrode borehole inclinometry data collected at DYE-3, Greenland. The methods were found convenient to use and it is claimed that the results represent physically reasonable approximations to the borehole geometry.

FREEZE THAW CYCLES, PERMAFROST PHYSICS, SALINE SOILS, GRAIN SIZE, SOIL TEMPERATURE, GROUND ICE, TESTS.

PERATURE, GROUND ICE, TESTS.

This report describes two new methods for computing borehole inclination and azimuth. In the first method borehole inclination and azimuth are assumed to vary linearly with are length. This results in an analytic model of the borehole inclination and azimuth or smooth. The second model, which takes borehole inclination and azimuth to vary quadratically with arc length between three measuring points, improves the smoothness of the model but the analysis must be carried out numerically. These models were applied to the installations. In all cases salt backfilling reduced the resistance to ground, with 175 ohms being the lowest obtained. Reductions varied from very small to an order of magnitude. Resistance also decreased over several seasons. Generally the greatest improvement and lowest values were obtained in the perennially frozen silt in interior Alaska. Data from colder silt suggest that salt backfilling will not be effective in arctic settings. Measurements at a partially theyed, coarse-grained site indicate that salt was moving much more rapidly (approximately five times as fast) away from the treated backfill than at the silt site in the CRREI.

EFFECT OF SEASONAL SOIL CONDITIONS ON THE RELIABILITY OF THE M15 LAND MINE

Richmond, P.W., et al, June 1984, 35p., ADB-085 452, In English and Chinese. 2 refs. Ho, S.C., Dittemore, H.R.

FROZEN GROUND STRENGTH, SOIL STRENGTH, MILITARY ENGINEERING, EXPLOSIVES, BLASTING, METEOROLOGICAL DATA, TESTS.

Inert M15 mines with live fuzzes were tested for functioning under four soil conditions (immediately after installation in July, and in November, January and April). The mines were installed using current emplacement doctrine and initiated by driving a tank over them. Results showed significant degradation in functioning rates during winter, which was attributed to frozen soil. A change in installation doctrine

the SNOW-TWO/Smoke Weck VI Field Experiment held
at Camp Grayling, Michigan, was a cooperative effort of
the U.S. Army Cold Regions Research and Engineering Laboratory and the Office of the Project Manager Smoke/Obscurants,
the main objective of which was to study the effects of
mannade and natural obscurants on the performance of
electro-optical and millimeter wavelength devices. This
report presents the results obtained by CRREL and some
20 other agencies during the SNOW-TWO phase of the
experiment, covering the periods 28 November to 21 December
1983 and 4 January to 9 March 1984. It is the fourth
in a series of data reports on the SNOW field experiment
sponsored by the U.S. Army Corps of Engineers Winter
Battlefield Obscuration Research Program. The report is
in two main volumes with a supplemental classified volume.
The first volume covers the general topics of meteorology
and snow characterization; the second covers the topics of
electromagnetic wave transmission through falling and blowing
snow, target/background signatures, and system performance
in snow.

RELATIONSHIPS AMONG BANK RECESSION, VEGETATION, SOILS, SEDIMENTS AND PER-MAFROST ON THE TANANA RIVER NEAR FAIRBANES, ALASKA.

Gatto, L.W., July 1984, 53p., ADA-152 332, 31 refs.

39-3030
BANKS (WATERWAYS), SOIL EROSION, PER-MAFROST DISTRIBUTION, VEGETATION, RIVER FLOW, SEDIMENTS, HYDRAULICS, UNITED STATES—ALASKA—TANANA RIVER. UNITED STATES—ALASKA—TANANA RIVEK.

The objective of this analysis was to determine if available data are useful in identifying the characteristics that contribute to evodibility of the banks along two reaches of the Tanana River. Risting data on bank vegetation, soils, sediments and permafrost were used.

Because these data were general and not collected for the purpose of sito-specific analysis, the analytical approach was simple and did not include any statistical tests. The data were visually compared to the locations and estimated amounts of historical recession to evaluate if any relationships were obvious. The results of this analysis showed no useful relationships.

IBSIS, ICE DEFORMATION.

A buckling analysis of cracked, floating ice sheets is presented; both symmetrical and unsymmetrical shapes were investigated. The finite element method was used for the in-plane analysis as well as the out-of-plane analysis. The results of the analyses of symmetrically shaped ice sheets are compared to those of previous analyses where a radial stress field was assumed for the in-plane stresses, and there is good agreement between them. The results of theoretical analyses are compared to analysis considerable in analysis. e compared to experimental data obtained in small-scale laboratory experime

CLIMATE AT CRREL, HANOVER, NEW HAMP-SHIRE.

Bates, R.E., Aug. 1984, 78p., ADA-148 400, 6 refs.

CLIMATE, METEOROLOGICAL DATA, SNOW-FALL, PRECIPITATION (METEOROLOGY), WEATHER STATIONS, FREEZING POINTS, DEGREE DAYS, UNITED STATES—NEW HAMPSHIRE—HANOVER.

SHIRE—HANOVER.

A 10-year climatological record of meteorological data collected at the CRREL meteorological station is presented for the period October 1972 through December 1982. Data presented include air temperature, heating and freezing degreedays, relative humidity, dew point, precipitation, snowfall, wind speed and direction, solar radiation and evaporation. Air temperature and precipitation monthly and annually are compared statistically to the 30-year normal and the period-of-record normal for Hanover, New Hampshire. The appearing produced the control of record. Some comparisons are made between the 10-year averages and the long-term normals.

SALT ACTION ON CONCRETE.

Sayward, J.M., Aug. 1984, 69p., ADA-147 812, Refs. p.52-57.

39-1040
CONCRETE PAVEMENTS, SALTING, CORRO-SION, FREEZE THAW CYCLES, DAMAGE, REINFORCED CONCRETES, WEATHERING, BRIDGES, CHEMICAL ICE PREVENTION, CRACKING (FRACTURING).

CRACKING (FRACTURING).

Serious deterioration of concrete bridges by delcing salts is generally sacribed to depassivation and corrosion of reinforcing steel, as growth of its corrosion products causes spalling, there, simple evaporative tests simulated the salt weathering that slowly crumbles rocks in nature, where crystals growing from pore water fed from below stress the matrix just as do ice crystals in frost heaving soil. Like needle ice (surface frost action in soil) the salt columns exuded from concrete also lifted tiny particles, signifying crumbling. Microcracks developed in 1-3 years of after-test dry storage.

**TOTAL Line and station DYE-1 was moved sideways 210

DEW line ice cap station DYE-3 was moved sideways 210 ft and placed on a new foundation in 1977, then raised

27 ft in 1978. Secondary forces within the structure steel framework were measured in 1978, 1981, 1982 an 1983. The overall level of secondary stresses had increase but through 1983 the columns were still within their stre but through 1983 the columns were still within their stress limitations. Some localized overstress is expected in 1984. The concept of using above-surface trusses to resist wind loads and brace the eight columns has proven to be satisfactory. It has eliminated the subsurface enclosures used in the past to protect subsurface trusses, enclosures that proved to be the structural weak link of the original facility; their elimination has resulted in a stronger facility that is easier to maintain. The measurements and findings of this program were used in the development of the design to extend the life of DYE-3 to be implemented in 1984. That work should reduce the level of secondary stresses in the frame.

DEUTERIUM DIFFUSION IN A SOIL-WATER-ICE MIXTURE.

Tice, A.1 39-1139

PROZEN GROUND PHYSICS, ISOTOPES, SOIL WATER MIGRATION, PHASE TRANSFORMA-TIONS, TESTS, LABORATORY TECHNIQUES.

An experiment was performed to determine the rate of equilibration of deuterium between the ice and liquid phases of water in partially frozen soil. The results of this experiment are consistent with a diffusion rate of deuterium ice of 1 or 2 ten-billionths sq cm/s. A method for calculating the approximate equilibration time, given the size of the ice crystals in the system, is provided. This calculation compares well with the experimental results.

COMPARISON OF THREE COMPACTORS USED IN POTHOLE REPAIR. Snelling, M.A., et al, Nov. 1984, 14p., ADA-149 937,

Raton R A

39-2099

ROAD MAINTENANCE, BITUMINOUS CON-CRETES, COMPACTION, EQUIPMENT, DENSI-TY (MASS/VOLUME), TEMPERATURE EF-FECTS.

This report is a summary of the results of a compaction study using recycled hot mix asphalt concrete conducted during August 1983 in an indoor facility at CRREL in Hanover, New Hampshire. This study compared three kinds of compactors for optimum performance, and also considered such factors as temperature of the asphalt concrete

mix, number of passes, size and depth of patches, and the number of lifts to fill the holes. Results showed that a vibratory roller and vibratory plate compactor could both compact patches to the desired 98% of laboratory density, but that a 200-lb lawn roller could not. Temperature of the hot recycled mix is critical, with 250F being the cut-off temperature. It was shown that if the mix is not compacted promptly after placement and is allowed to cool below 250F, proper compaction may not be attained.

BANKS (WATERWAYS), RIVER FLOW, SOIL EROSION, SEDIMENT TRANSPORT, FLOOD CONTROL, EMBANKMENTS, ENVIRONMEN-TAL IMPACT, AERIAL SURVEYS, PERMA-FROST, COUNTERMEASURES, UNITED STATES—ALASKA—TANANA RIVER.

STATES—ALASKA—TANANA RIVER.

The Tanana River changes character in the vicinity of Fairbanks, from the braided pattern upstream of North Pole to the anastomosing or irregular meander pattern downstream of the Chena River confluence. This transition in planform is accompanied by a marked decrease in gradient and a change in dominant bed material from gravel to sand. Within the past 50 years the river has been affected by a variety of human activities, including flood control works, access causeways and gravel entractions. The Phase III in river levee and groin construction constituted a strong local disturbance of the river system where local river slope was steepened and large quantities of bed material were put into transport from pilot channel enlargement as the river adjusted to the new alignment. As of the end of 1982, the full and final effects of this disturbance were not clear. Recommendations are given regarding impacts from human activities, alleviation of impacts, levee protection, further interpretive analysis and future monitoring of river behavior.

CATALOG OF CORPS OF ENGINEERS STRUC-TURE INVENTORIES SUITABLE FOR THE ACID PRECIPITATION-STRUCTURE MATERI-AL STUDY.

PRECIPITATION (METEOROLOGY), CHEMICAL PROPERTIES, CONSTRUCTION MATERIALS, ENVIRONMENTAL PROTECTION, DAM-AGE, BUILDINGS, COST ANALYSIS, COMPUT-ER APPLICATIONS.

ER APPLICATIONS.

This report contains a survey of Corps of Engineers floodplain inventories. Its purpose was to determine if enough building materials information was available in the Corps data base to be used for predicting the distribution of building materials across the country as part of the EPA acid rain assessment program. The floodplain surveys were rated using the criteria of the date of the surveys, the number of buildings, the variety of building materials, the amount of dimensions data listed for the buildings, the land cover types in the data, and whether or not the data were computerized. Six structure inventories are recommended for further study. SR 85-02

CONSTRUCTION MATERIALS, PRECIPITA-TION (METEOROLOGY), CHEMICAL PROPER-TIES, BUILDINGS, RAIN, FORECASTING.

TIES, BUILDINGS, RAIN, FORECASTING. Data bases on buildings in Revere and Quincy, Masschusetts, and Stamford, Connecticut, were studied to determine if a measure of building material distribution could be calculated for a city using land use, census tract and the Corpa' data on buildings. Statistical measures of chi-square, asymmetric lambda, uncertainty coefficient, F ordinate, as well as the correlation coefficient-squared and eta-swared statistics were calculated for the three data bases. The Corps definition of building type was found to be the best predictor of the building surface area. However, all indicators (including building type) explained only low percentages of the variability in the dependent variable (building surface area). These results indicate that other variables are required to explain the variability of building surface area adequately.

SR 85-08 STEFAN'S PROBLEM IN A FINITE DOMAIN WITH CONSTANT BOUNDARY AND INITIAL CONDITIONS: ANALYSIS.

Takagi, S., June 1985, 28p., ADA-158 558, 13 refs.

FROST HEAVE, BOUNDARY LAYER, STEFAN PROBLEM, ANALYSIS (MATHEMATICS).

PROBLEM, ANALYSIS (MAINEMATICS). Stefan's problem in a finite domain is solved under constant boundary and initial conditions. Starting in a semi-infinite domain, the solution passes infinitely many stages of lead times in a finite domain and finally becomes stationary. The singularity at the finite terminal necessitates introduction of lead times. Including lead times, parameters defining the solution vary with time. Only the analytical result is reported in this paper.

TREATMENT, WATER TREATMENT, FROST
PROTECTION, COUNTERMEASURES, DE-SIGN.

SIGN.

Freezing and other cold weather problems are a major cause of poor performance at wastewater treatment plants in cold climates. This report, based on experience in Alaska, in the north central U.S. and on a survey of over 200 treatment systems in northern New England, presents procedures and criteria so that designers can avoid cold weather problems in future systems. It also contains detailed guidance for assisting operators in overcoming current problems and deficiencies. The information is organized and presented in terms of the major process units that are likely to be found in a typical wastewater treatment system. A number of detailed case studies of problems and solutions at specific systems in northern New England are also included.

SK 85-12 SUITABILITY OF POLYVINYL CHLORIDE PIPE FOR MONITORING TNT, RDX, HMX AND DNT IN GROUNDWATER. Parker, L.V., et al, Aug. 1985, 27p., ADA-160 733, Refs. p. 19-22.

Jenkins, T.F., Foley, B.T. 40-1497

PIPES (TUBES), GROUND WATER, WATER POLLUTION, WATER CHEMISTRY, MATERIALS, TESTS, SALINITY.

ALS, TESTS, SALINITY.

A number of samples of commerical PVC groundwater monitoring pipe, which varied in schedule, diameter or manufacturer, were placed in contact with low concentrations of aqueous solutions of TNT. RDX, HMX and 2,4-DNT for 80 days under nonsterile conditions. Results indicated that there was some loss of TNT and HMX in the presence of PVC pipe compared to glass controls but that for the most part concentrations of analyte were equivalent between types of pipe.

A second experiment was performed to determine if the losses were due solely to sorption or if biodegradation was also a factor. This experiment was done under a variety of groundwater conditions by varying salinity, initial pH and dissolved oxygen. The only case where there was increased loss of any substance because of the presence of PVC pipe was in the TNT solution under nonsterile conditions. This increased loss was thought to be associated with increased microbial degradation rather than sorption. Therefore, given the length of time of this experiment and the small amount of loss attributable to sorption, PVC groundwater monitoring pipe is acceptable for monitoring groundwater for these munitions. Several samples of PVC pipe were also leached with groundwater for 80 days and no detectable interferences were found by reversed phase HPLC analysis.

CONSTRUCTION AND CALIBRATION OF THE OTTAUQUECHEE RIVER MODEL.
Gooch, G., Aug. 1985, 10p., ADA-159 902.

ICE JAMS, ICE BREAKUP, RIVER ICE, ICE FOR-MATION, MODELS, FLOODING, WATER SUP-PLY, TESTS.

The Ottauquechee River is located in west-central Vermont This river was chosen for a physical hydraulic model using This river was chosen for a physical hydraulic model using real ice. The model was built at a scale of 1:50 horizontal and 1:20 vertical.

After problems with modeling bed roughness and operating the pump system were overcome, the tests went smoothly. SR 85-15

SAMPLE DIGESTION AND DRYING TECHNIQUES FOR OPTIMAL RECOVERY OF MERCURY FROM SOLD AND SEDIMENTS. Cragin, J.H., et al, Sep. 1985, 16p., ADA-161 948, 9

Foley, B.T. 40-4456

SOIL CHEMISTRY, SEDIMENTS, METALS, DE-TECTION, CHEMICAL ANALYSIS, DRYING.

Mercury in soils and sediments can be accurately determined over the concentration range of 0.04 to 2 microgram Hg/g using amalgamation on thin gold films. Relative standard deviation of analysis is about 10%. A mild sample dissolution technique, involving HNO3 at 75C, produced quantitative Hg recoveries for certified sediment samples and recoveries equivalent to those of rigorous Parr-bomb digestions for other soil and sediment samples. Oven drying of samples at 150C resulted in significant losses of Hg from both soil and sediment samples. Air drying, oven drying at 60C or freeze drying resulted in Hg recoveries that agreed within 20% of those for undried samples. Thus, any one of these three comparable methods is recommended for Hg determinations in soils and sediments. Mercury in soils and sediments can be accurately determ

SR 85-18 SNOW IN THE CONSTRUCTION OF ICE BRIDGES.

Coutermarsh, B.A., et al, Oct. 1985, 12p., ADA-163 118, 6 refs. Phetteplace, G.

40-3269

40-3209 ICE CROSSINGS, MILITARY OPERATION, SNOW (CONSTRUCTION MATERIAL), SNOW COVER EFFECT, SURFACE PROPERTIES, ICE SURFACE, ICE COVER STRENGTH.

SURFACE, ICE COVER STRENGTH.

Snow's contribution as a wearing surface, leveling material or reinforcement to ice bridges is discussed. It is shown that it has limited value as a reinforcement and then only ys adding water and freezing the resulting slurry. Snow can be used effectively as either a leveling or wearing surface but natural ice thickening is inhibited by the insulating property of the snow. The snow should be of uniform depth and not mounded or windrowed to avoid deflecting the ice away from the water surface. This would substantially weaken the carrying capacity of the ice bridge.

ENVIRONMENTAL PROTECTION.

ENVIRONMENTAL PROTECTION.

A building material sampling program for the New Haven, connecticut, region was conducted in March and April of 1984 to examine the types and amounts of building surface materials exposed to acid deposition.

A stratified, systematic, unaligned random sampling approach was used to generate sample points across the five sampling frame are:

At least 107 sample points were examined per sampling frame to yield a total sample size of 576 points.

Building sizes, surface materials, roof characteristics, roof-mounted apparatus, chimneys, gutters, downspouts, fences and miscellaneous outdoor accessories were recorded.

This report provides an initial summary of the data collected. Sample sizes indicate that additional sampling is required to produce the desired 70 sites (with buildings) per frame.

POTENTIAL OF REMOTE SENSING IN THE CORPS OF ENGINEERS DREDGING PRO-GRAM.

McKim, H.L., et al, Nov. 1985, 42p., ADA-166 334, Refs. p.23-37.

Klemas, V., Gatto, L.W., Merry, C.J. 40-3271

DREDGING, REMOTE SENSING, AERIAL SUR-VEYS, CHANNELS (WATERWAYS), SEDIMENT TRANSPORT, SUSPENDED SEDIMENTS, ENVI-RONMENTAL IMPACT.

RONMENTAL IMPACT.

The potential of remote sensing in the Corps of Engineers Dredging Program for providing data on channel surveys, sediment drift and dispersion during dredging, water quality and suspended sediment concentrations, and selection of disposal sites and monitoring environmental effects at disposal sites was reviewed. The recommended remote sensor combination for recording dredging and environmental changes was a small, single-engine surveraft equipped with at least two 70-mm or 33-mm cameras. The first camera should be loaded with color film and the second camera with color infrared film for vesetation or land use manning, or passing the color of the color o infrared film for vegetation or land use mapping, or pan-chromatic film with special filters for water studies. For bathymetric mapping, the cameras will have to be supplemented by airborne impulse radar or laser profilers, and possibly sonar depth finders. A combination of small aircraft and boats is optimum for mapping currents and observing plume dynamics.

COMPARISON OF EXTRACTION TECH-NIQUES AND SOLVENTS FOR EXPLOSIVE RESIDUES IN SOIL.

Leggett, D.C. 40-3272

SOIL CHEMISTRY, EXPLOSIVES, SOIL POLLU-TION, ULTRASONIC TESTS, CHEMICAL ANAL-

Extraction of TNT, TNB, RDX and HMX from two soils was studied in terms of process kinetics and recovery. Two solvents, acctenitrile and methanol, and four extraction techniques, Soxhlet, ultrasonic bath, mechanical shaker and homogenizer-sonicator were compared. The results were complex in that some interactions among analyte, method and solvent were found. Acctonitrile was found to be clearly superior to methanol for RDX and HMX. Soxhlet and ultrasonic bath generally recovered more than homogenizers of shake and ultrasonic bath generally recovered more than homogenizers. clearly superior to methanol for RDX and HMX. Southlet and ultrasonic bath generally recovered more than homogenizer or shaker, although a complicating factor is that all techniques were not necessarily at equilibrium. In terms of sample throughput, the ultrasonic bath and ahaker are preferred over Southlet and homogenizer-sonicator. The ultrasonic bath generally approached equilibrium more rapidly than the shaker so it appears to be the best overall choice. Another complicating factor is that times to reach equilibrium were different for the two soils and for the different analytes. This points to the need for more kinetic studies on othe soils and sediments.

PRELIMINARY INVESTIGATIONS OF MINE DETECTION IN COLD REGIONS USING SHORT-PULSE RADAR.

Arcone, S.A., Nov. 1985, 16p., ADB-100 401, 10 refs. 40-3302

DETECTION, SNOW COVER EFFECT, RADAR ECHOES, MINES (ORDNANCE), DIELECTRIC PROPERTIES, FROZEN GROUND PHYSICS, PO-LARIZATION (WAVES), POLAR REGIONS.

EARLEATION (WAVES), FOLKER RECOUNTS.
Short-pulse roder is being investigated as a tool for detecting mines in cold regions. The specific problem is the detection of mines buried in a snowpack characterized by a dielectric constant. In this preliminary investigation air and frozen sand are used to roughly approximate the dielectric extremes of a dry snowpack. The radar signal used had a duration of 3-4 ns and a broad frequency spectrum centered near 800 MHz. The responses of mines suspended in air were first recorded as a function of polarization and orientation. Mine responses were then recorded for emplacement in a fairly homogeneous dielectric of frozen sand. The waveform amplitudes depended strongly on mine orientation and weakly on polarization. Resonance in air at all orientations and polarizations for a particular mine type were similar. F sponses in the sand were easily recognizable for an anten standoff of I m, but depended on target size. Investigation a snowpack are now beginning.

REGRESSION MODELS FOR PREDICTING BUILDING MATERIAL DISTRIBUTION IN FOUR NORTHEASTERN CITIES.

Merry, C.J., et al, Dec. 1985, 50p., ADA-166 335, 12 refs.

LaPotin, P.J. 40-3303

QUILDINGS, POLAR REGIONS, MODELS, DISTRIBUTION.

The Corps of Engineers conducted a field sampling program for inventorying building materials in the northeastern United States, and the data from the field program were compiled into a data base for statistical analysis.

Correlation coeffi-

cients were derived between the independent variables and the surface area of the five building material types. The correlation coefficients were used in an optimal stepries regression model developed for each material class for each city. A number of factors appear to be significantly associated with the distribution of building material exposure. How-ever, the variables do not correlate at levels required for constructing adequate predictive models that would be applica-ble to other sampling locations.

BLASTING, EXPLOSION EFFECTS, SHOCK WAVES, ATTENUATION, ANALYSIS (MATHEMATICS), POLAR REGIONS.

Air blast phenomena are reviewed and a digest of data is given, mainly in graphical form. To the extent possible, corresponding data are given for air blast in cold regions, provided that the prevailing conditions are significantly differ-ent from those of temperate regions.

USACRREL PRECISE THERMISTOR METER. Trachier, G.M., et al, Dec. 1985, 34p., ADA-166 470, 4 refs.

Morse, J.S., Daly, S.F. 40-3305

FRAZIL ICE, WATER TEMPERATURE, THER-MISTORS, ICE FORMATION, MEASURING INSTRUMENTS, ACCURACY.

STRUMENTS, ACCURACY.

To facilitate the study of frazil ice in the field, a highly accurate, portable water temperature meter was required. The USACRREL Precise Thermistor Meter was designed and built to meet this need. The meter is rugged, battery-operated, waterproof, and able to operate over a wide range of ambient temperatures. A unique feature of this instrument is the use of software to compensate for temperature-dependent variation in the analog electronics. The circuitry consists of an analog printed circuit board and a low power microcomputer. The resistance of a calibrated thermistor is determined and its temperature calculated using the Steinhart-Hart equation. The accuracy of the meter was determined both theoretically and in cold room tests. The hardware and software used in the meter are described.

REGIONS.

Trickling filters are found in about 50% of the operating wastewater treatment systems owned by the U.S. Army, and more are likely for any new construction. Control of nitrogen, particularly ammonia in wastewater effluents, is a growing necessity. Ammonia can be removed in trickling filters but the process is temperature-dependent. This study combined an intensive literature review with data collection at full-scale and pilot-scale systems. These results are presented and evaluated. A liquid temperature of at least 7 C is necessary in the filter bed for effective ammonia removal, and a separate single-purpose filter bed dedicated for nitrification is recommended when significant ammonia removal is required at cold regions locations. Criteria and equations are derived for future cold region system designs. designs.

UNITED STATES—NEW HAMPSHIRE.

This data report contains climatological measurements for the winters of 1980-81 and 1981-82 made at three sites in New Hampshire situated at elevations of 155 m, 870 m and 1910 m above sea level. Parameters measured

included wind speed and direction, precipitation, temperature, humidity, and duration of icing events. Comparison of the data provides the opportunity to examine the influence of elevation on atmospheric icing occurrence and intensity. In New Hampshire, icing appears to occur only at elevations above about 500 m.

FROZEN GROUND THERMODYNAMICS, PER-MAFROST HEAT TRANSFER, FROZEN GROUND MECHANICS, SOIL PHYSICS, SOIL MECHANICS, THERMAL CONDUCTIVITY, SOIL WATER, SOIL FREEZING.

SOIL WATER, SOIL FREEZING.

This monograph describes the thermal properties of soils, unfrozen or frozen. The effects on these properties of water and its phase changes are detailed. An explanation is given of the interaction between moisture and heat transfer. Other influences on soil thermal properties are described, including such factors as soil composition, structure, additives, saits, organics, hysteresis and temperature. Techniques for testing soil thermal conductivity are outlined and the methods for calculating this property are described. The monograph gives the results of an evaluation of these methods whereher their predictions were command with measured monograph gives the results of an evaluation of these methods whereby their predictions were compared with measured values, thus showing their applicability to various soil types and conditions.

CLE SIZE DISTRIBUTION, GRAIN SIZE.

Methods of determining the frost susceptibility of soils are identified and presented in this report. More than one hundred criteria were found, the most common based on particle size characteristics. These particle size criteria are frequently augmented by information such as grain size distribution, uniformity coefficients and Atterberg limits. Information on permeability, mineralogy and soil classification has also been used. More complex methods requiring pore size distribution, moisture-tension, hydraulic-conductivity, heave-streas, and frost-heave tests have also been proposed. However, none has proven to be the universal test for determining the frost susceptibility of soils. Based on this survey, four methods are proposed for further study. They are the U.S. Army Corps of Engineers Frost Susceptibility Classification System, the moisture-tension hydraulic-conductivity test, a new frost-heave test, and the CBR-after-thaw test.

RIDGES, ANALYSIS (MATHEMATICS).

The first part of the report provides an introduction to the mechanics of deformable solids, covering the basic ideas of stress and strain, rheology, equilibrium equations, strain/displacement relations, constitutive equations, and failure criteria.

Practure mechanics and fracture toughness are also reviewed to the second part of the report summarizes available data on the mechanical properties of freshwater ice and saline ice, accounting for the influences of strain rate and

loading rate, temperature, porosity, salinity, and grain size. Boundary value problems are not dealt with, but there is discussion of some miscellaneous topics, including thermal strains, behavior of brash ice, and pressure ridges. The report was written as a study text for a NATO Advanced report was written as a study text for a NATO Advanced Study Institute on Sea/Ice/Air Interactions, and was intended to be used in conjunction with companion texts on related

FRAZIL ICE DYNAMICS.

Daly, S.F., Apr. 1984, 46p., ADA-142 037, Refa. p.44-

PRAZIL ICE, ICE MECHANICS, ICE CRYSTAL GROWTH, ICE CRYSTAL NUCLEI, HEAT TRANSFER, ICE FORMATION, ICE PREVENTION, SUPERCOOLING, TURBULENT FLOW, ANALYSIS (MATHEMATICS).

ANALYSIS (MATHEMATICS).

To describe the dynamic evolution of frazil ice in turbulent natural water bodies, the basic equation for dynamic frazil crystal number continuity and the basic equation of heat balance for a differential volume are developed. Crystal growth and nucleation of new crystals are the major parameters in these equations. Expressions for the growth rate of frazil ice crystals are the major parameters in these equations. Expressions for the growth rate along the major axis is controlled by heat transfer. The heat transfer coefficient is a function of crystal size, the fluid urbulence, and the fluid properties. The magnitude of inertial and buoyancy forces on the ice crystals are determined as is their influence on the heat transfer. Spontaneous nucleation of ice can be discounted; accondary nucleation is responsible for the vast majority of frazil ice crystals. The theoretical rate of secondary nucleation is partially modeled as a function of the supercooling, fluid turbulence and crystal size distribution. A simple analytical solution of the basic equations is developed for the growth of frazil ice in a well-mixed, steady-state crystallizer.

M 84-02 ATMOSPHERIC ICING ON SEA STRUCTURES. Makkonen, L., Apr. 1984, 92p., ADA-144 448, Refs. p.77-92. 39-97

DELL SEA.

This monograph reviews essential aspects of sea ice dynamics of the Arctic and Antarctic on the geophysical scale and discusses the role of ice dynamics in air-sea-ice interaction. The review is divided into the following components: a) a discussion of the momentum balance describing ice drift, b) an examination of the nature of sea ice rheology on the geophysical scale, c) an analysis of the relationship between ice strength and ice thickness characteristics, and d) a discussion of the role of ice dynamics in the atmosphere-ice-ocean system. Because of the unique, highly nonlinear nature of sea-ice interaction, special attention is given to the ramifications of ice interaction on sea ice motion and deformation. These ramifications are illustrated both by analytic solution and by numerical model results. In addition, the role of ice dynamics in the atmosphere-ice-ocean system is discussed in light of numerical modeling experiments, including a fully coupled ice-ocean model of the Arctic-Oreenland-Norwegian seas.

M \$5-01 EROSION OF NORTHERN RESERVOIR SHORES. AN ANALYSIS AND APPLICATION OF PERTINENT LITERATURE Lawson, D.E., May 1985, 198p., ADA-157 811, Refs. p.137-191.

40-4448
SHORE EROSION, ICE COVER EFFECT, RESERVOIRS, SLOPE PROCESSES, PERMAFROST, SHORELINE MODIFICATION, GROUND WATER, WATER LEVEL, MODELS, WATER WAVES, FORECASTING, TEMPERATURE EF FECTS.

FECTS. This monograph describes the current state of knowledge of northern reservoir shore erosion, primarily by examining the results of erosional studies on lakes, coasts and rivers. The major erosional processes of reservoir beaches and bluffs and their mechanics are discussed in detail. Thermal and physical parameters affecting the erodibility of shores, the environmental impacts of erosion, and the basic characteristics of the unique reservoir environment are reviewed. Current models of shore zone development are also presented. This literature analysis revealed that knowledge of erosion and recession in northern impoundments is severely limited. Quantitative analyses of the processes of erosion and their relative importance, parameters determining the nature, rate and timing of erosion, and models to predict the erodibility of a shore for use in minimizing shoreline recession remain in need of basic field research.

MP 843 ON THE USE OF TENSIOMETERS IN SNOW

HYDROLOGY.
Colbeck, S.C., Journal of glaciology, 1976, 17(75), p.135-140, 11 refs.
30-3540

SNOW HYDROLOGY, MEASURING INSTRU-MENTS, WATER PRESSURE.

MENTS, WATER PRESSURE.

The construction and use of snow-water tensiometers is described. Water pressure at the base of a shallow, Arctic snow-pack was measured to illustrate the response of the basal layer to water percolation. Water tension above an ice layer and water flux through the ice layer were measured in glacial now. The gravity flow theory is used to explain the close agreement between these parameters. This suggests that the ice layer has little effect on the flow field and that gravity (rather than tension gradients) controls the flow. Further work on water tensions is needed to identify the role of tension gradients in ripening and shallow snow covers. (Auth.)

BOREHOLE INSTRUMENTS, ICE SHEETS, FLOW MEASUREMENT, MECHANICAL PROP-ERTIES, ANTARCTICA—BYRD STATION.

The drill hole at "Byrd" station, which was completed in Jan. 1968 to a vertical depth of 7063 ft (2153 m) below the top of the hole casing, was resurveyed in Jan. 1975 to a vertical depth of 4835 ft (1474 m). Inclination and azimuth measurements were made with a Parsons multiple to a vertical depth of 4835 ft (1474 m). Inclination and arimuth measurements were made with a Parsons multiple shot inclinometer and compared with the earlier measurements made during drilling. The results indicate a progressively increasing displacement with depth to a value of 51.2 ft (15.6 m) or about 7.3 ft/year (2.23 m/year) at the 4835 ft (1474 m) level. The direction of movement relative to the surface varies from acuth-west at 300 ft (91.5 m) to north-east at 1100 ft (335 m) to cast at 3368 ft (1027 m) to north-east at 4835 ft (1474 m), indicative of a complex twisting motion. An increase in accessible depth slong the hole axis of 18 ft (5.49 m) beyond the 1969 depth was noted. No attempt was made to measure the hole diameter or vertical strain. It is recommended that the hole be resurveyed in 3-5 years if it is still logistically feasible, using a more up-dated inclinometer. (Auth.) MP 847

GAS INCLUSIONS IN THE ANTARCTIC ICE SHEET AND THEIR GLACIOLOGICAL SIGNIFICANCE.

Gow, A.J., et al, Journal of geophysical research, Dec. 20, 1975, 80(36), p.5101-5108, 16 refs. Williamson, T.

30-2295

ICE SHEETS, DRILL CORE ANALYSIS, GAS IN-CLUSIONS, BUBBLES, AIR ENTRAINMENT, ICE PRESSURE, ANTARCTICA—BYRD STA-TION.

Cores obtained to the bottom of the Antarctic Ice Sheet at Byrd Station have been used to analyze some physical properties of the air bubbles trapped in the ice. These bubbles constitute the remnant air that is retained when polar snow transforms into glacial ice. Parameters measured include size, shape, abundance, and spatial distribution of bubbles, gas volumes, and bubble pressures and their variations with depth in the ice sheet. Bubbles occur abundantly

in the top 800 m of ice but then gradually disappear until they can no longer be detected optically below 1100 m. This disappearance is not accompanied by any significant loss of air from the ice, and the available evidence suggests that the air is retained in the form of a gas hydrate or clathrate. Because of the release of confining pressures following drilling, the hydrate begins to decompose soon after cores are pulled to the surface. This decomposition is accompanied by the growth of gas-filled bubblelike cavities that are easily distinguishable from original sir bubbles. Bubble pressure measurements show that (1) bubbles with pressures exceeding about 16 bars begin to relax back to this value soon after in situ pressures are relieved by drilling. (2) further slow decompression will occur with time, and (3) the rate of decompression is controlled to some extent by the intrinsic structural properties of the ice and its thermal and deformational history. Only small variations were observed in the entrapped air content of the ice cores; they probably reflect variations in the temperature and/or pressure of the air at the time of its entrapment. Only in ice from the bottom 4.83 m was the air content observed of air coincided precisely with the first appearance of straiffed moraine in the correct it is concluded that this ice originated in ice from the outcom 4.53 in was the air content concrete to decrease to trace amounts. Since this virtual absence of air coincided precisely with the first appearance of stratified moraine in the cores, it is concluded that this ice originated from the refreezing of air-depleted water produced under pressure melting conditions at the bottom of the ice aheet.

HEIGHT VARIATION ALONG SEA ICE PRES-SURE RIDGES AND THE PROBABILITY OF FINDING "HOLES" FOR VEHICLE CROSS-INGS.

SEA ICE, PRESSURE RIDGES, AIR CUSHION VEHICLES, ICE CROSSINGS, HEIGHT FIND-

sure ridges are major obstacles to vehicle mobility See ice pressure ridges are major obstacles to vehicle mobility in the Arctic Basin. An estimate of the expectation of holes of various heights and widths in the ridges is desirable for optimum vehicle design. This study uses probability theory and ridge shadow measurements from aerial photographs of sea ice to determine the distribution of holes of various heights and widths in pressure ridges. General conclusions are drawn regarding trafficability of this terrain for vehicles of various sizes.

MP 849 MEASUREMENT OF SEA ICE DRIFT FAR FROM SHORE USING LANDSAT AND AERIAL PHOTOGRAPHIC IMAGERY.

International Symposium on Ice Problems, 3rd, Hanover, New Hampshire, 18-21 August 1975. Proceedings, International Association of Hydraulic Research, 1975, p.541-554, 6 refs. Tucker, W.B., Weeks, W.F. 30-2755

SEA ICE, ABRIAL SURVEYS, PHOTOGRAMME-TRY, ICE DEFORMATION, DRIFT, LANDSAT.

TRY, ICE DEFORMATION, DRIFT, LANDSAT. This paper discusses recent work on the development of analysis procedures for obtaining drift and deformation measured from sequential visual imagery of sea ice that is located far from land. In particular for LANDSAT images far from land a semi automatic procedure for transferring the location coordinates of a common set of ice features from the Earth coordinate system of one image to another is discussed. Necessary inputs for the transfer are the location coordinates and latitude and longitude) of the center of each image and latitude and longitude) of the center of each image and the location of two arbitrary points on a known line of longitude; all this information is available from LAND-SAT, although with some error. These errors will produce remerious answerous amerent strains if velocities are estimated by simply SAT, although with some error. These errors will produce spurious apparent strains if velocities are estimated by simply taking position differences. With regard to measuring strain from sea ice aerial imagery without ground control, errors in such measurements are examined using uncorrected photographs. The errors in using such uncorrected imagery and using common undeformed ice floes to establish a common scale are found to be of the order of 1% whereas typical maximum differential motions are as large as 5%.

SEA ICE, PACK ICE, ICE DEFORMATION, ICE PRESSURE, OFFSHORE STRUCTURES, ICE CONDITIONS, STRESSES, ICE NAVIGATION, STATISTICAL DATA.

Past studies of statistics of pressure ridges have supplied useful information on the nature of pressure ridge height and spacing distributions as well as information on accompanical and temporal variations in ridging. These statistics should be of some aid in the construction of Arctic offshore structures and in icobreaking and shipping operations. By coupling these height and spacing statistics with information on ridge lengths, the amount of detouring necessary to avoid ridges may be estimated. Closely associated with ridging are drift and deformation studies. Two aspects of these studies applicable to this conference are (1) the prediction of the rate of opening and closing of the pack ice, and (2) estimation of typical geophysical stresses in the ice pack. Theoretical and experimental work at CRREL indicates that certain approximate rules may be invoked to estimate the divergence rate far from coastal boundaries, namely that in winter the pack ice should diverge in reasonably well localized high pressure systems, whereas in summer the ice typically diverges in low pressure systems. As regards estimates of geophysical stresses, estimates from a variety of sources suggest that maximum stresses integrated through the pack ice thickness are of the order of 10,000 to 100,000 N/m. The upper limit is approximately equal to the force required to crush 0.25-meter-thick as a ice.

CONTINUOUS MONITORING OF TOTAL DIS-

SOLVED GASES, A PEASIBILITY STUDY.
Jenkins, T.F., Gas Bubble Disease Conf-741033, Battelle, Pacific Northwest Laboratories, Richland, Washington, Oct. 8-9, 1974, Proceedings, 1975, p.101-105,

31-1900 BUBBLES, WATER, GAS INCLUSIONS, SURVIV-AL, EXPERIMENTATION, MONITORS.

Ap preliminary investigation was undertaken to determine if a continuous analyzer could be configured to monitor dissolved gases in natural waters. A three-component system was designed consisting of a pumping system, a continuous stripper, and a detector. Prototypes of the first two components were assembled and evaluated under field conditions. Based upon these results, it is possible to configure an unattended near-continuous monitor to measure total dissolved eased. ed, near-continuous monitor to measure total dissolved gas concentration in natural waters.

IDENTIFICATION OF NUCLEI AND CONCEN-TRATIONS OF CHEMICAL SPECIES IN SNOW CRYSTALS SAMPLED AT THE SOUTH POLE. Kumai, M., Journal of the atmospheric sciences, May 33(5), p.833-841, 16 refs. 30-3647

SNOW COMPOSITION, CLAY MINERALS, SNOW CRYSTAL NUCLBI, ANTARCTICA— SOUTH POLE.

SOUTH POLE.

A total of 380 electron micrographs and electron diffraction patterns of 93 mow crystal nuclei were analyzed in this observation. The nuclei were identified as mainly clay minerals and sodium chloride particles. The clay mineral nuclei were lilite 20%, knotine 3%, halloysite 4%, vermicuite 3%, and related minerals 24%. For the other nuclei, sodium chloride accounted for 5%. Fifteen percent of the snow crystals did not appear to have nuclei. Therefore, all nuclei found in anow crystals were terrestrial substances from oceans and continents. The shapes of snow crystals were single bullets, combinations of bullets, and hexagonal hollow columns. The snow crystals formed at temperatures from 30 to -35C. The snow crystals formed at temperatures from 50 to 100 mm. The mean mass concentration of sodium chloride in snow crystals was 40.6 ppb and that of clay minerals was 15.4 ppb. The sodium chloride nucleus concentration coincided within the experimental error with data taken from the chemical analysis of the South Pole snow cover made by several workers. It was concluded that most of the sodium chloride contained in the South Pole snow cover was due to the sodium chloride nuclei of snow crystals.

OPTICAL PROPERTIES OF SALT ICE

Lane, J.W., Journal of glaciology, 1975, 15(73), Symposium on Remote Sensing in Glaciology, Cambridge, 16-20 September, 1974, p.363-372, 12 refs., In English with French and German summaries. Includes 30-2349

SALT ICE, ICE OPTICS, LIGHT SCATTERING. SALT ICE, ICE OPTICS, LIGHT SCATTERING. The dependence of the extinction coefficient on salinity was investigated for both NaCl-ice and sali-tice made from natural sea-water. Specimens were prepared under a variety of conditions and examined over the wavelength range 4,000 to 8,000 A. The effects of scattering from air bubbles trapped in the ice were examined for ice made from distilled water. It was found that the method of preparing samples markedly affected their structure, but that, when prepared in the same manner, salt-ice made from natural sea-water and NaCl-ice did not show significantly different transmission properties. It was found that, for a wavelength of 6328 A, the data could be fit to the relation ker_1i.67-0.85 exp (-0.27x)/cm within an uncertainty of 26%, where ke is the extinction coefficient, and x is the salinity of the ice in g/kg. Within an uncertainty of 10%, there was no variation in transmission for ice at the same temperature and salinity over the wavelength range 4000 to 8000 A. salinity over the wavelength range 4000 to 8000 A measurements were made at a temperature of -200C.

MP 855 MECHANISMS OF CRACK GROWTH IN

MECHANIOWAN QUARTZ. Martin, R.J., III, et al, Journal of geophysical research, Dec. 10, 1975, 80(35), p.4837-4844, 21 refs. Durham, W.B.

Jurnam, w.B.

30-3068

ROCKS, CRACK PROPAGATION, WATER
TRANSPORT, QUARTZ.

A previous study of time-dependent crack growth in singlecrystal quartz has been expanded to examine the possibility
of microfracturing events during stable crack growth, to
look for evidence of plastic deformation associated with
crack propagation, and to determine the dependence of crack
growth on crystallographic orientation. No discernible effect
of orientation on the temperature or change in applied streas
or partial pressure of water dependencies during sequential
crack growth episodes was observed, and no correlation
was found between observed microfracturing events and the
rate of crack propagation. However, the magnitude of
the applied stress to achieve the desired rates of crack
extension did vary with orientation. No evidence of plastic
deformation has been found in samples of quartz undergoing
time-dependent crack growth at temperatures up to 250C.
Some Dauphine twins have been observed at temperatures
above 125C. The fact that the stress, temperature, and water
dependencies are independent of orientation is interpreted to
suggest that the observed time-dependent cracking is controlled
by the transport of water to the crack tip.

ICE CORING DRILLS, DRILLING, ROTARY DRILLING, THERMAL DRILLS.
Drilling systems are discussed in general terms, component functions common to all systems are identified, and a simple classification is drawn up in order to outline relations between penetration, material removal, hole wall support, and ground conditions. Energy and power requirements for penetration of ice and frozen ground are analyzed for both mechanical and thermal processes. An electromechanical coring drill has been used for deep drilling in Greenland and Antarctica. Thermal drills have also been used for boring holes in ice although they are not as efficient, in energetic terms, as mechanical drills. Power requirements for removal of material and for hoisting of drill strings are considered, and total power requirements for complete systems are assessed. Performance data for drilling systems working in ice and frozen ground are reviewed, and results are analyzed to obtain specific energy values. Specific energy data are assembled for drag-bit cutting, normal impact and identation, liquid jet attack, and thermal penetration. Torque and axial for capabilities of typical rotary drilling systems are reviewed and analyzed. The overall intent is to provide data and quantitive guidance that can lead to systematic design procedures for drilling systems for cold regions. (Auth. mod.) design proced (Auth. mod.)

COMPUTER SIMULATION OF THE SNOW-MELT AND SOIL THERMAL REGIME AT BAR-ROW, ALASKA.

Outcalt, S.I., et al, Water resources research, Oct. 1975, 11(5), p.709-715, 17 refs. For another version

COMPUTERIZED SIMULATION, SNOW TEM-PERATURE, SOIL TEMPERATURE, THERMAL DIFFUSION, SNOW FENCES, WATER SUPPLY.

An annual anow-soil simulator for arctic tundra was developed by using coupled models of surface equilibrium temperature and substrate thermal diffusion. Soow ripening, melt, and accumulation are modeled in the simulator which is forced with daily weather data. The simulator predicts that a now fence array capable of producing drift deeper than 4.2 m will initiate a permanent snowfield at Barrow. Alsaka. Such a man-induced snowfield could serve as a reliable source of freshwater for Barrow and similar villages in the north slope region of Alsaka. Further analysis indicated that albedo reduction due to dust fall, snow removal, etc., is dominant over aerodynamic effects in producing the early spring meltout observed at Barrow Village.

MP 858 FORCES ON AN ICE BOOM IN THE BEAU-HARNOIS CANAL.

HARNOIS CANAL-Perham, R.E., et al, International Symposium on Ice Problems, 3rd, Hanover, New Hampshire, 18-21 Au-gust 1975. Proceedings, International Association of Hydraulic Research, 1975, p.397-407, 7 refs.

ICE BOOMS, SHEAR STRESS, ICE PRESSURE, LOADS (FORCES).

LOADS (FORCES).

Ice booms are used to hasten the formation of a stable ice cover in early winter. Their main function is to reduce the area of open water where large amounts of ice floes and frazile ice can be generated. This ice, if uncontrolled, can cause an ice jam or blockage at power house intakes and restrict its generating capacity. A particular function of the forebay ice boom of the Beauharnois Power House is to prevent any ice upstream from moving down into the forebay. In the winter of 1974-75 CRREL obtained force measurements of both cross stream and downstream components in the forebay ice boom. The purpose of this paper is to report these forces and their variations. A limited amount of supplemental data such as water flow, ice thickness, and canal dimensions is provided. All of the information should help in the understanding of interaction between an ice boom and its ice cover.

ICE PRESSURE, HYDRAULIC STRUCTURES, PILE STRUCTURES, MODELS, LABORATORY

TECHNIQUES.
Laboratory tests on freshwater ice were conducted by using model structures of various geometries. Vertical and sloping pile sections with diameters up to 36 in. (91.4 cm) were pushed through the ice with an active testing system. The test variables investigated were size, shape, velocity, and slope or angle from the vertical. The data gathered in this study indicates that nominal ice pressure varies indirectly with pile width/ice thickness (D/T) ratio in the range of 1:10. There was no apparent change in nominal ice pressure due to the change of the pile shape. Data gathered in the velocity tests suggests an inverse effect upon the ice pressure, especially at speeds greater than 3 in/s (7.6 cm/s). In the sloping pile tests it was found that the ice pressure decreased with an increase in the sloping pile tests that failed in bending was developed. Values for this linear correlation were found graphically. A comparison of the test results with other investigations is also presented.

TATION, ALPINE SOILS.
This study characterizes upland forest stands in interior Alaska and compares and contrasts their organic and soil properties. Stand data are presented for tree and sapling species in three aspen/birch and four black spruce stands. Litter layers had greater mass and were more acidic beneath sapen/birch contained higher concentrations of C, N, P, Ca, Mg, Mn, and Zn than did black spruce organic layers. Organic layer K and Fe concentrations were similar beneath the two stand groups. Total organic layer N, P, and Zn mass were similar in the two stand groups, more Ca, Mg, and Mn were present beneath hardwoods, and more K was present beneath black spruce. Extractable soil P decreased rapidly with increasing profile depth beneath aspen/birch stands, but increased with depth to a maximum at or below 15-30 cm beneath hardwoods than beneath coniferous communities. Soils beneath the two stand groups could not be consistently separated by differences in pH, %C, %N,

or C/N ratio. Percentage soil carbon at all depths and in all stands was closely correlated with %N (r=0.97) and CEC (r=0.98).

Rand, J.H., Ice core drilling, edited by J.F. Splettstoesser, Lincoln, University of Nebraska Press, 1976, p.133-137, 1 ref.

ICE CORING DRILLS, DRILLING, FIRN.

ICE CORING DRILLS, DRILLING, FIRN.

The USA CRREL shallow drill is an electromechanical device designed for continuous coring in firm and ice to a depth of 100 m. The drill bores a 14-cm-diameter hole while obtaining a core 10 cm in diameter at a penetration rate up to 1 m/min in -20C ice. The cuttings are transported by spiral brush auger flights to a container above the corestorage section. The core and cuttings are removed from the drill after each 1 m run. Additional components include: 100 m of a seven-conductor electromechanical cable, a 6.8-m tower, a hoist which is ski-mounted, and a three-phase 220-V AC gasoline generator. All the equipment has been designed to be transported in a Twin Otter ski-equipped plane and assembled and operated by two men. The total weight of the drill and associated components is \$18 kg. The minimum estimated time required to drill 100 m and retrieve core is 15 hours. Excellent core was obtained in a record drilling time of 15 h from a 100-m hole drilled in early Nov. at the South Pole under the new geodesic dome. A second 100-m hole was drilled on the Ross Ice Shelf. the new geodesic dome.

POLAR ICE-CORE STORAGE FACILITY. Langway, C.C., Jr., Ice core drilling, edited by J.F. Splettstoesser, Lincoln, University of Nebraska Press, 1976, p.71-75, 8 refs. 30-3482

ICE CORES, COLD STORAGE.

ICE CORES, COLD STORAGE.

The U.S. Army Cold Regions Research and Engineering Laboratory (USA CRREL) has responsibility for the central storage and curatorial activities of the ice cores recovered in the Office of Polar Programs/National Science Foundation (OPF/NSF) Arctic and Antarctic research programs. The main purpose of the central ice-core storage facility is to handle, process, catalog and distribute the ice cores drilled in the polar regions to OPF-approved recipients for glaciological research. Under the agreement with OPF, the ice cores are stored at CRREL and in a commercial freezer facility at Littletown, N.H.; a technician handles and catalogs them. A core data bank is maintained for retrieval and information exchange, and starting with the Dys 3 ice core, is being computerized. The storage facilities are described. Recent developments include a cooperative analysis program between CRREL, the University of Copenhagen, and the University of Bern, a particle analysis lab, a core stratigraphy and logging routine, and a surface pit/ice-core correlation system.

MP 875 HOVERCRAFT GROUND CONTACT DIREC-TIONAL CONTROL DEVICES.

Abele, G., International Hovering Craft, Hydrofoil and Advanced Transit Systems Conference, 2nd, Amsterdam, May 17-20, 1976. Proceedings, London, Kalerglic Publications, 1976, p.51-59, 6 refs. 31-1996

31-1990 ALL TERRAIN VEHICLES, AIR CUSHION VEHI-CLES, VEHICLE WHEELS, ENVIRONMENTAL IMPACT, TUNDRA TERRAIN, IMPACT.

CLES, VEHICLE WHEELS, ENVIRONMENTAL IMPACT. TUNDRA TERRAIN, IMPACT.

The maneuverability of a hovercraft can become a serious operational problem where the craft's travel route is restricted by obstacles or requires close-quarter turns, and during travel on slopes and in crosswind conditions. While improvement and perfection of serodynamic methods may be a more desirable approach, there is a practical limit to these methods, and the use of ground contact devices requires consideration to provide more positive directional control. Wheels deserve special attention, and therefore are analyzed in more detail because of their obvious application on a variety of land terrains. Brake rods and harrows are more suitable on water, ice and snow. The saucer would cause the least ecological impact on fragile organic terrains such as tundra. The use of controlled ground contact with skirt sections having retractable rollers or special wearing surfaces may represent the least significant change to the basic design of the craft or its components. The relative directional stability is evaluated in terms of the total yswing moments produced by a variety of wheel arrangements (single, dual, tandem), location on the craft, and operational modes (frevolling, braked, or a combination of the two). The available moments are plotted against the yaw angle of the craft to determine the most effective operational mode with a particular wheel arrangement for any yaw condition. The analysis is limited to retractable devices which act as moment-producing brakes or rollers and do not serve as either propulsion or load support aids.

SPREAD OF CETYL-1-C14 ALCOHOL ON A MELTING SNOW SURFACE.

Meiman, J.R., et al, International Association of Scientific Hydrology. Bulletin, Sep. 1966, 11(3), p.5-8, 3 refs. Microform No. SIP 25051. Slaughter, C.W.

SNOW SURFACE, SNOW PERMEABILITY, SNOW MELTING, DISTRIBUTION, SNOW EVAPORATION.

The primary objective of the study was to gain information on the rate of spread of cetyl alcohol on a melting snow surface. Point applications of radioactive cetyl-1-C14 alcohol were placed on the surface of snow contained in cubical wooden boxes 25 cm on each side. The boxes with snow were placed in a controlled environment of 2C and with a relative humidity of 95%. Under the study conditions cetyl alcohol spread as far and 10 cm within and with a relative humidity of 95%. Under the study conditions, cetyl alcohol spread as far as 10 cm within 1 hr and 15 min. Distribution of the alcohol over the surface was highly variable. (Auth.)

ON THE DETERMINATION OF HORIZONTAL FORCES A FLOATING ICE PLATE EXERTS ON A STRUCTURE.

Kerr, A.D., Journal of glaciology, 1978, 20(82), p.123-134, 26 refs. 32-4451

ICE PRESSURE, ICE LOADS, ICE COVER STRENGTH, STRUCTURES, LOADS (FORCES),

FLOATING ICE.

At first, the general approach for calculating the horizontal forces an ice cover exerts on structures is discussed. Ice-force determination consists of two parts: (1) the analysis of the in-plane forces, assuming that the ice cover remains intact; and (2) the use of a failure criterion, because an ice force cannot be larger than the force capable of breaking up the ice cover. For an estimate of the largest ice force, an elastic plate analysis and a failure criterion are often sufficient. A review of the literature revealed that in the majority of the analyses, it is assumed that the failure load is directly related to a "crushing strength" of the ice cover. Observations in the field and tests in the laboratory show, however, that in some instances the ice cover failed by buckling. Subsequently, the ice-force analyses based on the buckling failure mechanism are reviewed, and their shortcomings are pointed out. A new method of analysis, which is based on the buckling of a floating ice wedge, is then presented.

SNOW COVER, RUNOFF, MODELS, CANADA-LABRADOR.

LABRADOR.

A physically based model of the movement of water through snowpscks was used to calculate hydrographs generated by diurnal waves of anowmelt on the tundra and in the boreal forest of subarctic Labrador. The model was tested against measured hydrographs from hilliside plots that sampled a range of aspect, gradient and length, vegetative cover, and snow depth and density. The model yielded good results, particularly in the prediction of peak runoff rates, though there was a slight overestimate of the lag time. A comparison of predictions with field measurements indicated that given the ranges over which each of the controls is likely to vary, the two most critical factors controlling the hydrograph are the snow depth and the melt rate, which must be predicted precisely for short time intervals. Permeability of the mowpack is another important control, but it can be estimated closely from published values.

BEARING CAPACITY OF FLOATING ICE PLATES SUBJECTED TO STATIC OR QUASI-STATIC LOADS.

Kerr, A.D., Journal of glaciology, 1976, 17(76), p.229-268, Bibliography p. 263-268, In English with French and German summaries.

FLOATING ICE, BEARING STRENGTH, STATIC LOADS, BIBLIOGRAPHIES.

This paper contains a critical survey of the literature on the bearing capacity of floating ice plates. It consists of a discussion of general questions, a critical survey of analytical attempts to determine the bearing capacity of floating ice plates and a survey of field and laboratory tests on floating ice plates and their relation to the analytical results. It concludes with a systematic summary of the results, a discussion of observed shortcomings, and suggestions for needed investigations.

SNOW STRENGTH, SNOW COVER STABILITY, MEASURING INSTRUMENTS, TRAFFICABILITY, SHEAR PROPERTIES.

A new, portable one-man operated instrument was developed to simplify the measuring of snow properties required for evaluating the trafficability of a snow over and to predict vehicle performance. The 16-lb instrument with interchangeable plates of various sizes is capable of providing data for computing the vertical strength armsters remarkers. changeable plates of various sizes is capable of providing data for computing the vertical strength parameters n and k and the horizontal strength parameters c and l. The vertical load is applied manually, the predetermined contact pressures are indicated by a system of signal lights connected to a force control switch type force gage, the manually (push-button) activated torque motor for the shear test is driven by a 12-volt battery. A second man is needed to record sinkage and torque data during the test.

SOME EFFECTS OF AIR CUSHION VEHICLE OPERATIONS ON DEEP SNOW.

Abele, G., et al, International Conference on Terrain-Vehicle Systems, 4th, Stockholm, April 24-28, 1972. Proceedings. Vol.2, Stockholm, Sweden, 1972, Proceedings. V p.214-241, 2 refs. Parrott, W.H.

AIR CUSHION VEHICLES, SNOW DEPTH, ERO-SION, SURFACE PROPERTIES, TESTS.

SION, SURFACE PROPERTIES, TESTS.

Travel with an Sk-5 ACV over soft anow results in surface deformation/erosion of a few inches, caused primarily by rear skirt drag; on windswept snow only scratches can be seen. During hovering on soft snow, deformation below the cushion chamber usually does not exceed a few inches. The action of the air flow (escape velocity 70 to 120 ft/sec) produces a 1-ft ditch below the peripheral skirt in less than a minute; thereafter the extent of crosion does not increase appreciably during continued hovering. A partial seal between the inner face of the skirt (above fingers) and the snow surface may exist, arresting further acttling of the vehicle. Relatively cohesive layers of snow such as windslabs and crusts are not croded. A level snow cover, regardless of how deep or soft, does not appear to be capble of immobilizing an ACV of this and larger size. Some operational problems and their degree of severity, such as visibility, snow accumulation and adhesion to vehicle, skirt drag, effect of terrain surface porosity and presence of vegetation, are also discussed.

THERMAL ANALYSIS, FROZEN GROUND PHYSICS, UNPROZEN WATER CONTENT, CLAY MINERALS, ICE WATER INTERFACE, LOW TEMPERATURE TESTS.

The author discusses the low temperature behavior of several samples of frozen soils taken from the dry valleys of Antarctica. The samples were composed of various clay minerals and had varying water contents.

It is demonstrated that some of the water remains unfrozen and that there is a dependency between the unfrozen portion and the surface area of the sample. It was pointed out that problems arising from the umfrozen water content of soils are of great interest to CRREL researchers as is the analysis of ice cores from Greenland and Antarctica as a technique for establishing past climates and in predicting future climates. The author discusses the low temperature behavior of several

OVERVIEW OF LAND TREATMENT FROM CASE STUDIES OF EXISTING SYSTEMS.

ANALYSIS, CLIMATIC FACTORS.

Wastewater treatment by land application is described for sites at Calumet, Michigan (88 years); Quincy, Washington (20 years); Manteca, California (11 years); and Livermore, California (8 years). All sites meet on an average the USPHS drinking water limit of 10 mg/l for NO3-N. Preapplication treatments vary for the site: Calumet, undisinfected, no treatment; Quincy, undisinfected, primary treatment; Manteca, undisinfected, secondary treatment and Livermore, disinfected, secondary treatment. The preapplication treatment and total operation and maintenance costs are: 3c/1000 gallons for Culmet, 20c/1000 gallons for Quincy, 27c/1000 gallons for Calumet, 20c/1000 gallons for Livermore. Although minor individual site problems are discussed and solutions presented, the authors conclude that land application offers year round treatment alternatives within variable climates.

—ALASKA—COOK INLET.

The purpose of this investigation was to analyze surface circulation, suspended sediment distribution, water-type migration, and tidal flushing mechanisms, utilizing medium and high altitude aircraft and repetitive synoptic satellite imagery with corroborative ground truth data. LANDSAT-1 and -2 and NOAA-2 and -3 imagery provided observations of surface currents, water type migrations and sediment and sea ice distributions during different seasons and tides. NASA NP-3A and U-2 aircraft multispectral imagery was used to analyze coastal processes, i.e., currents and sediment dispersion in selected areas.

Ground truth data were utilized in the interpretation of the sirroraft and satellite imagery. uspersion in selected areas. Ground truth data were utilized in the interpretation of the aircraft and satellite imagery and verified many of the regional circulation patterns inferred from the suspended sediment patterns apparent on the imagery. Several local circulation patterns not previously reported were identified.

WASTE TREATMENT, WATER TREATMENT, WATER CHEMISTRY, SEEPAGE, SOIL CHEMIS-TRY, WASTE DISPOSAL.

The capacity of a slow infiltration land treatment system to renovate wastewater in cold regions was investigated using six outdoor test cells. The principal mechanisms for nitrogen to renovate wastewater in cold regions was investigated using six outdoor test cells. The principal mechanisms for nitrogen removal were found to be plant uptake and denitrification; phosphorus was removed by plant uptake and immobilization in the surface soil layer; heavy metals were removed by sorption or precipitation in the top few centimeters of soil. Nitrogen removal was found to be seasonally dependent, the greatest losses occurring in the spring and summer and the least during fail and winter. This was due to the absence of plant uptake during winter and the effect of temperature on the conversion of ammonium to nitrate nitrogen clirification, which caused significant amounts of NIM4 to temperature on the conversion of ammonium to nitrate nitrogen (nitrification), which caused significant amounts of NH4 to be stored during winter and released in spring, giving rise to a period of high NO3 concentration in the leachate. Application of 15 cm/wek of secondary effluent to sandy loam soil resulted in diminished water quality (>10 mg/d of nitrate-N) during most of the year. With the exception of this heavy treatment experiment, heavy metals and phosphorus were confined to the top 15 cm of the soil. Application of effluents containing ppm levels of heavy metals to forages did not appear to cause phytotoxic effects. As for other water quality parameters (organic-C, BOD, suspended solids, fecal coliform) renovation of the wastewater was essentially complete. tially complete.

ITONS. Using available atmospheric pressure and ocean current data and estimating non-local stress transferral through the ice cover by employing a viscous drift model in the infinite boundary limit, predicted drift rates for one Russian and two U.S. drifting stations are made over the time period May 1962 to April 1964. The viscosity values giving the best fit between observed and predicted values show a reseasured winter increase that correlates well with the the best fit between observed and predicted values show a pronounced winter increase that correlates well with the ice growth rate. Phaically this suggests that ice drift rates (for a given wind field) tend to decrease in winter because of increased stress transferral through the ice cover. An empirical linear relationship between viscosity and ice growth rate is derived which yields predictions in reasonable agreement with both long (yearly) and short term (monthly) observed drift rates.

GROUND ICE, ICE LENSES, SOIL WATER MI-GRATION, FROZEN GROUND THERMODY-NAMICS, SOIL PRESSURE.

NAMICS, SOLL PRESSURE.

A new freezing mechanism, called segregation freezing, is proposed, to explain the generation of the suction force that draws pore water up to the freezing surface of a growing ice lens. The segregation-freezing temperature is derived by applying thermodynamics to soil mechanics concept that distinguishes the mechanically effective pressure from the mechanically neutral pressure. The frost-heaving pressure appears in the solution of the differential equations for the simultaneous flow of heat and water, of which the segregation-freezing temperature is one of the boundary conditions.

PERIODIC STRUCTURE OF NEW HAMP-SHIRE SILT IN OPEN-SYSTEM FREEZING.

McGaw, R., International Symposium on Frost Action in Soils, Lulea, Sweden, Feb. 1977. Proceedings, Vol.1, University of Lulea, 1977, p.129-136, 2 refs. 31-2074

SOIL FREEZING, SOIL STRUCTURE, WATER TABLE, GROUND ICE.

TABLE, GROUND ICE.

The periodic frozen structure of a glacially-deposited silt soil is analyzed using a metric grouping of sizes. Four specimens were frozen simultaneously in open-system freezing with initial water tables ranging from 15 cm (6 in.) to 105 cm (42 in.). Rate of freezing varied from near zero to 0.80 mm/hr. Measurements on the average thickness of individual ice layers and residual soil layers are tabulated and graphed for each specimen, with water-table depth and rate-of-freezing as independent variables. The data show that the ice-layer thickness decreases continuously with freezing rate for each of the four water-table depths. The maximum ice-layer thickness (4.5 mm) occurred with the highest water table and the slowest freezing. In contrast, the residual soil layer develops a maximum thickness for this soil in the 0.30 to 0.40 mm/hr range of freezing rates. The peak value (2.5 mm) occurred with water table depths of 45 cm (18 in.) and 75 cm (30 in.). In addition, the two specimens with the highest water tables developed a major secondary peak at very slow rates of freezing (less than 0.10 mm/hr), giving evidence of a separate mode of freezing.

BORNE PHOTOGRAPHY, ENVIRONMENTS, UNITED STATES—NEW ENGLAND.

The utility of satellite, high altitude and low altitude aerial imagery is presently being critically evaluated by the Corps of Engineers. The most significant contribution to date has been to increase confidence limits by more accurately estimating parameters used in models. Within the last three years several new cooperative remote sensing programs addressing environmental and hydrologic problems have been implemented. The objectives of these programs were to determine the availability, type, scale and resolution required and to show how remote sensing methods can be utilized to augment or update conventional procedures. Imagery from LANDSAT mission provided valuable information for size evaluation, definition of geologic lineations and monitoring snow and ice accumulation and ablation. The Skylab program has defined the detail of land use mapping that can be accomplished from the \$190A and \$190B photography. Low altitude aircraft photography (scale 1:33,600) was used to determine the location of materials at a potential dam construction site which could allow a large cost saving for transportation of material as compared to original design estimates. In another program, the effect of inundation at six New England flood control reservoir was investigated. The extent and severity of tree damage were mapped and analyzed statistically. These results will be used by the Corps in the reservoir management program.

EVALUATION AND RECOMMENDATIONS
FOR SNOWDRIFT CONTROL AT FAA ILS
FACILITIES, BARROW AND DEADHORSE,
ALASKA, FINAL REPORT.

Calkins, D.J., U.S. National Aviation Facilities Experimental Center. Report, Sep. 1976, FAA-NA-76-165, 41p., ADA-030 401.

31-2585 SNOWDRIFTS, SNOW FENCES, UNITED STATES—ALASKA—BARROW, UNITED STATES—ALASKA—DEADHORSE.

STATES—ALASKA—DEADHORSE.

The existing snowdrifting conditions are described at the Barrow and Deadhorse airfields and recommendations made for minimizing the drifting snow at the ILS facilities. The problem of drifting snow at the localizer and glide slope facilities was a result of the structures themselves creating drifts and causing outages. The most economical method of eliminating the problem at the glide slope was relocation of the instrument shelters such that they are not in line with the antenna masts and the prevailing wind direction. The localizer snowdrifts were caused by the bulkiness of the supporting structure carrying the antenna; although a selevated on piles severe turbulence develops behind the structure and the snow deposits. Wooden snowfences, 10 ft high, in parallel rows 200 ft apart will control the snow during an average snow year. Model studies of each alternative method were carried out to validate the various proposals. (Auth.)

VATOR PRESSURE OF 2.4.6-TRINITROTOL-UENE BY A GAS CHROMATOGRAPHIC HEADSPACE TECHNIQUE.

may logically be conducted within the larger context of entire drainage basins—Research Watersheds.

These are catchments which represent major environmental settings (e.g., Arctic tundra, subarctic taiga) and are specifically dedicated to research.

The hydrologic cycle of a complete catchment considered from precipitation through basic, yield provides a functional and conceptual base for considering mass, nutrient, and enterey transfer questions released to research. a functional and conceptual base for considering mass, nutrient, and energy transfer questions relevant to ecosystem functioning. With proper planning and execution, advantages to be gained may include: economy of effort, better cooperation between disciplines, improved application of results to real-world problems, and enhanced potential for comparative studies among circumpolar settings. In high latitudes, where climate, transportation and logistics, available scientific manpower, and lack of good background data often combine to render research both difficult and expensive, increased efficiency through integration of complementary biological and physical studies is especially attractive. In 1974-75 a start was made toward such a circumpolar program. Through the International Hydrological Decade (IHD), initial meetings of Swedish, Canadisn, and U.S. scientists have considered objectives of facilitating communication and data exchange, and ultimately improving understanding of hydrologic functioning in high-latitude environments. In Alaska exchange, and ultimately improving understanding of hydrologic functioning in high-latitude environments. In Alaska the 104-sq-km Caribou-Poker Creeks Research Watershed provides one example of multi-disciplinary, multi-agency research into environmental and hydrological behaviour of subarctic uplands, with provision for physical and biological investigations and experimentation. Similar circumpolar efforts should prove useful in a wide variety of discipline-specific and integrated scientific efforts.

Murmann, R.P., et al, Waste Management Conference, 8th, Rochester, N.Y., April 28-30, 1976. Proceedings, Rochester, N.Y., 1976, 36p., 21 refs. Iskandar, I.K.

WASTE TREATMENT, WATER TREATMENT, SOIL CHEMISTRY, WATER CHEMISTRY, IRRIGATION, UNITED STATES—WASHINGTON—QUINCY, UNITED STATES—CALIFORNIA—

MANTECA.

Evaluations of long-term systems for wastewater disposal on land by slow infiltration at Manteca, California, and Quincy, Washington, are presented. Factors considered include site history, operational characteristics. Domestic undisinfected wastewater has been applied at these locations by flood irrigation for up to 20 years. At Manteca, forage vegetation (rye grass) has been continuously maintained while at Quincy a crop rotation has been practiced. The system at Quincy has been relatively heavily loaded by application of approximately 15 cm/A (6 in./A) per week while at Manteca an average of only 4.5 cm/A (1.8 in./A) of wastewater has been applied per week. At both sites a control field and two disposal fields were investigated for comparison. Representative soil samples were collected at intervals to a depth of 150 cm. These were analyzed for about 30 pertinent chemical parameters including total and plant-availsthent chemical parameters including total and plant-availa-heavy metals. Soil solution samples were collected 30- and 160-cm depths with suction lysimeters. Pretreatment water samples, peripheral drainage water and ground water samples were also collected. All water samples were analyzed in the fields for pH. NH4-N, NO3-N and ortho-P during three periods in 1974.

PROPOSED SIZE CLASSIFICATION FOR THE TEXTURE OF FROZEN EARTH MATERIALS. McGaw, R., 1975, 10p., Presented at Les problèmes posés par la gélifraction. Recherches fondamentales et appliquées. Colloque interdisciplanaire, Paris-Le Havre, 23-25 April, 1975. Report No.311. 4 refs. 23-25.6 32-626

FROZEN GROUND, SOIL STRUCTURE, CLAS-SIFICATIONS, GROUND ICE.

SIFICATIONS, GROUND ICE.

The macroscopic fabric, or texture, of frozen earth materials represents a point-by-point summation of the microscopic nucleation, moisture flow, and heat flow around and between individual mineral particles. As such, frozen texture is intimately related to the basic mechanisms of ice segregation. A study of the details of frozen texture can lead to fundamental new knowledge on the formation and structural effects of segregated ice. A size classification derived from laboratory tests is proposed for the systematic measurement of the segregated ice. A size classification derived from isboratory tests is proposed for the systematic measurement of the characteristic (banded) element of interleaved soil and ice in fine-grained granular materials. Graphs are presented showing the relationship between the frozen texture of New Hampshire Silt and measured values of freezing rate as determined by the 0 C isotherm.

LAKE ICE, RADAR PHOTOGRAPHY, ICE WATER INTERFACE, ICE SOLID INTERFACE, ICE COVER THICKNESS, REFLECTIVITY, UNITED STATES—ALASKA—NORTH SLOPE. UNITED STATES—ALASKA—NORTH SLOPE. Side-looking airborne radar (SLAR) imagery obtained in April-May 1974 from the North Slope of Alaska between Barrow and Harrison Bay indicates that tundra lakes can be separated into two classes based on the strength of the radar returns. Correlations between the areal patterns of the returns, limited ground observations on lake depths and water compositions, and information obtained from LANDSAT imagery strongly suggest that areas of fresh-water lakes giving weak returns are frozen cumpletely to the bottom while areas giving strong returns are not. This is a reasonable interpretation inasmuch as the reflection coefficient associated with the high-dielectric rins as a the reflection coefficient associated with the high-dielectric-contrast ice-water interface would be roughly twelve times that associated with the low-contrast ice-soil interface brackish lakes also give weak returns even when they are

not completely frozen. This is the result of the brine present in the lower portion of the ice cover limiting the penetration of the X-band radiation into the ice. The ability to separate tundra lakes rapidly and easily into these two classes via SLAR should be useful in understanding wide variety of problems.

SNOW COVER EFFECT, MILITARY OPERA-TION, MILITARY EQUIPMENT.

TION, MILITARY EQUIPMENT.

Pertinent properties of a snow cover are thicknesses of individual layers, snow density, hardness, grain sizes and temperatures. A snow cover is subject to constant metamorphism and its occurrence is subject to seasonal and geographic distribution. A snow cover is a serious obstacle for traffic, especially military transportation. As a material, snow may be used for shelters, camouflage and fortification. Observations of attenuation of fast projectiles and fragments are reported. It is concluded that snow may be a material seriously affecting fuze mechanisms of certain projectiles and may degrade ammunition effects. Cited and recommended literature covers most of the aspects of the role of anow in warfare. MP 927

UTILITIES, PIPELINES, PLASTICS, POWER LINE ICING, FROST PROTECTION.

This report represents information on utility distribution systems gathered on a study trip to Scandinavia and Great Britian and Iceland. The information concerns new technology and materials in cold weather related problems and solutions

The distribution systems involved are: water and sewage times, vacuum sewage and pneumatic solid waste collection lines, heat distribution lines and electrical transmission, lines. aton lines. In Sweden much information was obtained on plastic pipes for water and a ewage lines and frost penetration protection. There are large district heating systems in operation and much information was found on heat distribution pipe systems and long distance heat transmission. In Norway, where almost all electricity is produced by hydroelectric stations, information was collected on electric transmission line using problems and self supporting aerial cables for electrical distribution. A wealth of information was gathered in London where the water and sewage systems are among the oldest and largest in the world and where some material and methods have a long history of success and other new ones are being introduced. District heating In Sweden much information was obtained

technology is also highly developed in London, but large systems have not yet evolved. Pneumatic solid wastes collection systems are being introduced.

SOIL CHEMISTRY, WEATHERING, MINERALOGY, X RAY ANALYSIS, ELECTRON MICROSCOPY, ANTARCTICA—BEACON VALLEY, ANTARCTICA—WRIGHT VALLEY.

Results are reported of an investigation by scanning electron microscopy (SEM) and energy dispersion X-ray analysis (EDXA) of the morphology, degree of weathering, and chemical species of six samples of soils from Beacon Valley, lateral valley adjoining Beacon Valley, and lower Wright Valley. EDXA revealed 11 elements in the soil samples: Valley. EDXA revealed 11 elements in the soil samples: sodium, magnesium, aluminum, silicon, suftur, chlorine, potassium, calcium, titanium, manganese, and iron. Chromium, palladium, and gold, used in shadowing, were also found. A typical SEM of soil from Beacon Valley showed rounded grains, which had been subjected to much mechanical and chemical weathering. Chemical species identified by EDXA for the soil of Beacon Valley is shumic, saline soil. EDXA of the soil of Beacon Valley is shumic, saline soil. EDXA of the soil of first lateral valley revealed a quartz particle showing weathering, with contamination by Na, Ca, and Fe, and CaSO4. The ahumic, saline soil of lower Wright Valley shows grains with sharp edges, indicating weak weathering and thus a relatively young age. Magnetite and silicate were found, and Fe, CaC12, and KC1 were identified using EDXA. BDXA

SNOW VEHICLES.

Trafficability of terrain is a function of soft soil, hard or rough ground, geometric obstacles, vegetation, and the riverine environment. All of these terrain aspects are altered by cold temperatures and snow cover. This paper examines the effect of snow cover on obstacle crossing performance of vehicles. The mathematical expressions describing step negotiation, trench crossing, and slope climbing on snow covered obstacles are given in terms of tracked vehicle, obstacle, and snow parameters. Tests of two tracked vehicle. obstacle, and snow parameters. Tests of two tracked vehicles on snow covered slopes, stream crossings, steps and trenches were conducted, and some of the results were compared with computed values. Differences between computed and

experimental values are attributed to neglecting alip-sinkage and track deflection in the computations. (Auth.)

REMOTE SENSING OF ACCUMULATED FRA-ZIL AND BRASH ICE.

Dean, A.M., Jr., National Hydrotechnical Conference, Jean, A. M., Jr., National Hydrotechnical Contention, and (with the participation of the Municipal Section), Quebec, May 30-31, 1977. 51-34-34 FRAZIL ICE, ICE CONDITIONS, REMOTE SENSING, ICE COVER THICKNESS, IMPACT STRENGTH, AERIAL RECONNAISSANCE, COMPUTER APPLICATIONS, ICE NAVIGA-TION.

The use of a broad-banded impulse radar system for aerial detection of accumulated frazil and brash ice in a 9.5 km reach of the St. Lawrence River is described. The impact of excessive frazil ice accumulation on the extended navigation season and on power generation is discussed. Equipment and technique are evaluated, while the data are presented as a contour map of ice thickness.

AIR PHOTO INTERPRETATION OF A SMALL

DenHartog, S.L., National Hydrotechnical Conference, 3rd (with the participation of the Municipal Section), Quebec, May 30-31, 1977. Proceedings, Université Laval, Canadian Society for Civil Engineering, 1977, p. 705-719, In English with French summary.

ICE JAMS, ICE MECHANICS, PHOTOINTER-PRETATION, VI PHOTOGRAPHS. VELOCITY, SLOPES, AERIAL

PHOTOGRAPHS.

Air photos of a small ice jam on the Pemigewasett River near Plymouth, N.H., were taken three days after the jam and compared with photos taken after the ice went out. The winter photos show a marked and sudden decrease in flow size apparently indicative of faster and longer movement of the ice. The spring photos show a number of shallows and obstructions that apparently had no effect on the ice movement. It is concluded that this jam was caused by a change in slope and subsequent reduction in velocity.

NUMERICAL SIMULATION OF AIR BUBBLER

NUMERICAL SIMULATION OF AIR BUBBLER SYSTEMS.
Ashton, G.D., National Hydrotechnical Conference, 3rd (with the participation of the Municipal Section), Quebec, May 30-31, 1977. Proceedings, Université Laval, Canadian Society for Civil Engineering, 1977, p.765-778, In English with French summary. 7 refs. 31-3438

BUBBLING, ICE PREVENTION, ICE CONTROL, HEAT TRANSFER, MECHANICAL ICE PREVENTION, EQUIPMENT, ANALYSIS (MATHEMATICS).

EMATICS).

The use of air bubbler systems to suppress ice formation is a technique which has been applied in a variety of situations and with varying degrees of success. Recently two-dimensional line source bubbler systems were analyzed (Ashton, 1974) in an effort to make available a tool which may be used in the design of a bubbler installation. That analysis was a steady-state evaluation of the melting rate of an ice cover above a bubbler system predicted on the basis of the input variables (depth, air discharge rate, water temperature). In actual operation, however, a bubble "sees" changing conditions such as diurnal and longer-term weather conditions, varying water temperatures, and depletion of the conditions, varying water temperatures, and depletion of the available thermal reserve. The simulation presented herin uses the steady-state analysis developed earlier (Ashton, 1974) uses the steady-state analysis developed earlier (Ashton, 1974) and steps it in time with each new condition determined from the results of the previous time step. In this sense the analysis herein may be considered quasi-steady. Results of the simulation are presented for an example case for a winter in Duluth, Minnesots and illustrate selection of time step size, effect of various strategies of intermittent operation, and variation in width of open water area with changing weather conditions.

SEA ICE, ICE COVER THICKNESS, MEASUR-ING INSTRUMENTS, RADAR ECHOES.

ING INSTRUMENTS, RADAR ECHOES.
Results obtained with a unique dual-antenna impulse radar system used to profile first- and multi-year sea ice near Prudhoe Bay, Alaska, are discussed. A description of the radar system is given along with representative field data. From the radar impulse travel times obtained with the use of dual antennas, calculations of thickness, electromagnetic impulse velocity and effective dielectric constant of the ice were made. Ice thicknesses determined by direct measurement and those calculated using the radar impulse travel times were found to be in good agreement. Continuous ice thickness profiles obtained with the radar were analyzed to provide representative cross sections of first-year and multi-year sea ice. These cross sections reveal the undulating bottom surface relief of both ice types. Calculations are presented that indicate a significant amount of oil could be trapped within this bottom relief should the oil be released under the ice from a sea-floor oil-production system.

FROZEN GROUND CHEMISTRY, SOIL WATER, SOIL CHEMISTRY, UNFROZEN WATER CONTENT, ION DIFFUSION.

Soils of continental Antarctica are forming in one of the most severe terrestrial environments. Continuously low most severe terrestrial environments. Continuously low temperatures and the scarcity of water in the liquid state result in the development of desert-type soils. In an earlier experiment to determine the degree to which radioactive NaCl36 would migrate from a shallow point source in permarket, movement was observed. To confirm this result, a similar experiment involving Na22Cl has been conducted. Significantly less movement of the Na22 ion was observed. Ionic movement in the unfrozen interfacial films at mineral surfaces in frozen ground is held to be important in chemical weathering in Antarctic and other desert soils.

The Barrow environment can be characterized as follows:
(1) Situated at the northern extremity of the Arctic Coastal
Plain, it has a climate consisting of long, dry, cold winters
and short, moist, cool summers. The latter is moderated
by the influence of the Arctic Ocean. (2) Vegetation
is meadow-like with an abundance of sedges, grasses, herbs
and a few dwarf shrub species. (3) Soils are predominantly
wet, with an average seasonal thaw of approximately 40
cm. (4) Perennially frozen ground underlies the entire
land surface coastal plain sediments are marine in origin
and mid- to late-Pleistocene in age. (6) The tundra landscape
is characterized by active geomorphic processes such as lake
erosion, polygonal ground formation and frost stirring of
the soil.

SNOWMELT, RUNOFF, SOLAR RADIATION, WATER FLOW.

Water flow through the unsaturated portion of a snowpack Water flow through the unsaturated portion of a snowpack is calculated using various assumptions about radiation penetration into the snow. The results show that for the purposes of hydrologic forecasting, it is sufficiently accurate to assume that all of the radiation absorption occurs on the surface. The error in the calculation of flow is largest for very shallow snowpacks but this error is reduced by radiation absorption at the base of the snow and by the routing of meltwater through the saturated basal layer.

FATE IN THE GREENLAND ICE SHEET. Herron, M.M., et al, Geochimica et cosmochimica acta, July 1977, 41(7), p.915-920, 22 refs. Langway, C.C., Jr., Weisa, H.V., Cragin, J.H. 1979, 197

ICE SHEETS, CHEMICAL ANALYSIS, METALS,

GREENLAND.

Chemical analyses of surface snow and dated deep ice core samples from Central Greenland suggest that Zn, Pb and sulfate are presently being deposited there at two to three times the natural rates. No recent increases in Cd or Veoncentrations were observed. Pre-1900 ice shows no measurable effect of the activities of man and represents a good natural serosol baseline. High enrichment factors relative to average crustal material were observed for Zn, Pb, Cd and sulfate in all samples indicating a natural source other than continental dust is responsible. A high temperature process or vapor phase origin for these enriched elements, possibly volcanism, seems likely.

RADIATION, ABSORPTT TTY.

The construction of embankments on permafrost, particularly in regions where the mean ground temperature is close to the melting point, usually results in melting of the permafrost which may cause excessive settlement. The depth of melting (thaw penetration) is considerably increased should the surface of the embankment be covered with a bituminous pavement. This increased melting results from greater absorption of solar radiation by the dark surface. A light-colored surface (white traffic paint) has been used on the asphalt runway at Thule AB, Greenland (a cold permafrost site) and on highway test sections near Fairbanka, Alaska (a warm permafrost site). The selection of light-colored surfacing materials for embankments on permafrost can have a considerable benign influence on the depth of thaw penetration and ultimately thaw consolidation.

MP 955 PERMAFROST EXCAVATING ATTACHMENT FOR HEAVY BULLDOZERS.

32-292 EXCAVATION, FROZEN GRAVEL, FROZEN CROUND STRENGTH.

CROUND STRENGTH.

In anticipation of military needs for grading and excavating frozen ground, an attachment for heavy engineer tractors was developed. The attachment consists of a hydraulically driven horizontal cutter drum that attaches to buildozer push arms, together with an auxiliary power source that attaches to the rear of the tractor. The machine is intended to break up frozen soils on that it can be handled by conventional earthmoving equipment. Tests in frozen gravel and in rock outcrops demonstrated that the machine and its cutting picks could withstand the most severe cutting conditions that would normally be met. In frozen gravel, cutting rates at a drum operating depth of 1.0 ft (0.3 m) averaged 1.5 ft/min (7.6 mm/s) at a 30-rev/min drum speed and 1.7 ft/min (8.6 mm/s) at 15 rev/min. Operating at the same depth in frozen silt, cutting rates averaged 1.8 ft/min (9.1 mm/s) at both 30-rev/min and 15-rev/min drum speeds; however, cutting rates varied considerably at the lower drum (2.1 mm/s) at one 30-120-110m and 12-120-110m unit specus;
speed. Modifications suggested for future designs include changes in the tooth lacing pattern and changes in the method of attaching the drum to the tractor.

BUILDINGS, HEAT LOSS, STEAM, PUMPS, MEASUREMENT.

MEASUREMENT.

The steam heat used in a combination dormitory and office building at Eielson AFB, Alaska, was measured over a 303-day period using a counter on the condensate return pump. The general relationships between pump cycle frequency and condensate flow were derived. This information was used to calibrate the system and express condensate flow and heat use with the number of pump cycles per hour. The heat used by the building consisted of a constant load for water heating and heat loss within the building and a variable load for space heating. The variable space-heating load was strongly controlled by the outside sir temperature and apparently consists of two temperature-dependent heat loss mechanisms. The first is conduction through the walls. It is speculated that the second is open-window air exchange for ventilation and to control room temperatures. The condensate pump cycle counter proved to be an inexpensive means of measuring steam use suitable for engineering and energy conservation studies. Further studies of actual heat consumption by various types of buildings in Alaska are recommended.

Urea-formaldehyde (UF) foam was investigated for use as an insulation retrofit material in very cold regions. A test installation of the material was made in stud frame walls at Fort Greely, Alaska in August 1975. Two months

later, a nondestructive survey of these walls employing thermopiles, thermocouples and an infrared camera revealed a marked improvement in the wall's insulating performance. Cuss in test areas eight months later revealed excellent filling and showed shrinkage to be under 2%. The implications of these and other findings for the suitability of foam as an insulation retrofit material are discussed. We are cautiously optimistic that UF foam has good potential for use in very cold resions. tiously optimistic that in very cold regions.

ICB BOOMS, ICB CONTROL, RIVER ICE, LOADS (FORCES), COST ANALYSIS, ECONOM-

LOADS (FORCES), COST ANALYSIS, ECONOMICS.

In early winter, ice booms are used to assist nature in quickly forming a solid ice cover on rivers. The open water, insulated in this way, is no longer the source of frazil ice which, in the past, has caused ice jams, flooding, and the loss of electrical generating capacity. They function in other ways as well such as strengthening the ice sheet edge against subsequent damage and restraining its movement. Ice booms are basically lines of floating timbers or poutoons held in place by heavy cable structures connected to buried anchors. They were developed and are used mainly by hydroelectric power groups but they also help facilitate ahip navigation in winter. The cost of these ice control devices over the past 17 years has ranged from about \$48/ft (\$156/m) to \$333/ft (\$1034/m) with one set costing approximately \$1,500,000. The value of many ice booms can best be related to the cost of replacing the electric power that could be lost if they were not present, as opposed to trying to choose a cost basis for a flood. A rough estimate of \$0.01/kWh for the value of replacement power is used here. The most valuable ice boom could be the Lake Rite Ice boom which saves an estimated \$13,000,000 per year. Next are the ice booms on the Beauharnois Canal which are used with particular operating techniques to save approximately \$4,300.000 per year. Ice boores can also help as we rillions. used with particular operating techniques to save approximately \$4,300,000 per year. Ice booms can also help save millions in shipping costs as well by stopping excessive ice movements during the navigation season in winter on the Great Lakes.

SHORE STRUCTURES.

A recently completed bridge across the Yukon River, north of Fairbanks, Alaska, provides an opportunity for studying breakup processes and measuring ice forces on a structure in a major river where ice conditions are near the continental extreme. Above the bridge the river flows through the 200-mile long Yukon Flats, a marshy, lake-dotted area. The multiple channels of the river meander back and forth providing a very large water surface for winter ice production. The winters are long and severely cold with only light snowfall so the Flats produce very large quantities of thick ice which pass through the bridge each spring. The bridge is a six-span continuous orthotropic-deck structure spanning a 2,000-foot channel. Five reinforced concrete piers secured to bedrock with prestressed rock anchors are subject to 2,000-foot channel. Five reinforced concrete piers secured to bedrock with prestreased rock anchors are subject to river ice. Steel legs rise from the tops of the piers to carry the deck. USACRREL, University of Alsaka, and Alsaka Department of Highways personnel observed ice-bridge interactions during the 1976 breakup. Time lapse and regular speed Super 8 movie and 35mm still photographs were taken. Several types of ice failure were observed including crushing along the full width of the piers, splitting, combined splitting and crushing and non-failure.

Infrared gas analytical techniques have made it possible to detect small amounts and changes in carbon dioxide in the environment.

The reliability and intercomparison of these measurements depends on the ability to calibrate the IRGA with a high degree of precision and accuracy. A mutual comparison scheme is presented to provide a method for calibrating an infrared gas analyzer and to document changes that occur in CO2 reference gas standards. It is suggested that a need exists to establish a central reference gas laboratory for the purpose of supply investigators with accurate reference gas standards. (Auth.)

WASTEWATER TREATMENT IN COLD RE-GIONS.

Uiga, A. 32-1274 WASTE TREATMENT, WATER TREATMENT, MILITARY FACILITIES.

MILITARY FACILITIES.

Westewater treatment at remote military installations in Alaska presently consists of aerated lagoons and extended aeration package plants. Although performance data for these systems are either very limited or in most cases nonexistent, indications are that most of these systems can not meet secondary effluent criteria as defined by the EPA. Processes for upgrading to meet the new criteria must be as simple as possible to design, build and operate. In particular, the requirements for operation and maintenance should be minimal due to the remote, isolated nature of most of the camps. Processes which appear to be feasible include land application, intermittent filtration, and variations of ponding.

Data have been presented on the growth and chemical composition of forages when influenced by various application rates of wastewater during 1974 and 1975. The results above that the greatest average annual forage yields and N and P removal occurred at the highest application rate of 5 cm/wk). However, forage removal efficiency of applied N and P was greatest at the lowest application rate of 5 cm/wk. At this rate an average of 97 percent of the applied N and 35 percent of the applied P was contained in the forage. Analyses performed in 1974 and 1975 ahowed a reduction in the levels of K in the soil and forage in 1975, relative to 1974, which indicates a requirement for K fertilization for sustained productivity. The reduction in K was related to the large quantities of this element required by crops and its low concentration in the wastewater. Soil analyses also showed reductions in soil pH and total exchangeable cations to levels which could be corrected by liming.

WASTE DISPOSAL, SOIL CHEMISTRY, MICRO-ELEMENT CONTENT, PLANTS (BOTANY), LAND DEVELOPMENT, SOIL POLLUTION, GRASSES, METALS.

GRASSES, METALS.

Heavy metal accumulation in soils and forages of a slow infiltration prototype land treatment system over a two year period is discussed. Uptake of heavy metals by plants and soils varied according to the amounts applied, soil type, and mode of wastewater application. Charlton silt loam soil retained more heavy metals than Windsor sandy loam. Heavy metals were confined to the top 15 cm of the soil and vertical movement occurred only in the soil from the treatment receiving the highest application rate (15 cm/wk). Movement of heavy metals in this treatment was thought to be due to a redistribution of organic matter (hydraulic effect), a decrease in soil pH or both. Forages (quack grass) from all the treatments contained much higher conceneffect), a decrease in soil pH or both. Forages (quack grass) from all the treatments contained much higher concentrations of heavy metals than the control. There were significant differences in plant tissue heavy metal accumulation between the different cuts. This was related to the concentration of heavy metals in the applied effluent. Forages from the second cut contained Cd and Ni and to some extent Cu at "toxic" levels, while Zn, Cr, Hg and Pb were present in normal or slightly higher amounts. Spray irrigation of heavy metal-spiked wastewater resulted in much higher concentrations in the plant tissue than in those from flood irrigation treatments. This could be due to absorption of heavy metals by the leaves in the sprayed forages. MP 978

CYCLES, PERMEABILITY.
Fine-grained dredged material obtained from disposal sites in the Great Lakes region was subjected to controlled freeze-thaw cycling in a special laboratory consolidometer. Volume changes and permeabilities were observed after full consolidation and freeze-thaw cycling for applied pressures in the range of 0.93 to 30.73 kPs. It was observed that as much as 20 percent or more volume reduction results when much as 20 percent or more volume reduction results when fredged material with liquid limits in the range of 60 to 90 percent is subjected to one cycle of freezing and thawing. The degree of overconsolidation by freezing and thawing appears to decrease with increasing amounts of coarse materials and with increasing plasticity. The vertical permeability of all materials examined was increased as much as two orders of magnitude, the greatest increase in permeability occurring for the fine-grained materials at the lowest stress levels.

MP 979 WASTEWATER REUSE AT LIVERMORE, CALI-FORNIA.

Uiga, A., et al, Cornell Agricultural Waste Management Conference, Ithaca, N.Y., 1976. Proceedings. Land as a waste management alternative. Edited by R.C. Loehr, Ann Arbor, Mich., Ann Arbor Science 1977, p.511-531, 24 refs. Iskandar, I.K., McKim, H.L.

WASTE TREATMENT, WATER TREATMENT, WATER CHEMISTRY.

WATER CHEMISTRY.

Wastewater reuse occurs at Livermore, California by application of treated effluent to a golf course, to a farminand to an airport area and to a stream. Salinity problems occurred on the clay soils of the golf course because requirements for daily site soccess and wastewater application were contradictory. The effluent was successfully reused at the agriculture site and disposal area. The outfall discharge increased the total dissolved solids of the receiving water and discharged large quantities of chlorine. Soil chemical and discharged large quantities of chlorine. Soil chemical analysis showed that exchangeable sodium percentage, total phosphorus, soluble phosphorus, pH, and organic carbon were changed but not critically by effluent reuse. The changes, except in pH, could be explained by existing agronomic techniques for irrigation in a semi-arid climate.

WATER VAPOR, ADSORPTION, LOW TEMPER-ATURE TESTS, CLAY MINERALS, MARS (PLA-NET).

A large amount of interest has recently been expressed pertaining to the quantity of physically adsorbed water by the Martian regolith. Thermodynamic calculations based on experimentally determined adsorption and desorption isotherms and extrapolated to subzero temperatures indicate therms and extrapolated to subzero temperatures indicate that physical adsorption of more than one or two monomolecular layers is highly unlikely under Martian conditions. Any additional water would find ice to be the state of lowest energy and therefore the most stable form. To test the validity of the thermodynamic calculations, we have measured adsorption and desorption isotherms of sodium montmorillonite at -5C. To a first approximation it was found to be valid.

ROOF LOADS RESULTING FROM RAIN ON SNOW; RESULTS OF A PHYSICAL MODEL. Colbeck, S.C., Canadian journal of civil engineering, Dec. 1977, 4(4), p.482-490, In English with French summary. 11 refs. See also 32-1151 (CR 77-12). 32.1649

32-1648
ROOPS, SNOW LOADS, RAIN, MATHEMATI-CAL MODELS.

A physical model is used to calculate roof loads due to rain on a snow covered roof. A snow depth of 0.5

m and the twenty-five year rainstorm in Hanover, New Hampshire, are used in the examples. For a flat roof with 10 m parallel flow to gutters, the total liquid weight can increase the roof load by about 50%. The weight of the transient liquid is greatly increased in the mode of flow is radial to contral drains and is decreased if the roof is slightly inclined or if significant melt channels form in the basal layer. However, the wetting of the anow over its entire depth will still cause a significant weight of transient liquid. Snow drifting can cause very large, local loads but the effects of snow temperature and antecedent moisture are not too important. Depending on the circumstances, the largest load can occur for either a long duration, low intensity rainstorm or a short duration, high intensity rainstorm. The former occurs if the saturated layer makes a significant contribution to the total live load whereas the latter occurs when the liquid weight is due mainly to the unsaturated layer. Purther study is needed to establish the joint probabilities of combined snow and rain loads, especially when rain and snowmelt occur simultaneously.

values reconstruction of the viscous approach is made by comparing predicted with observed ice drift in the Arctic basin over a two-year period employing a viscous constitutive law having both bulk and shear viscosities. Numerical drift calculations for the Arctic Basin are carried out at 4-day intervals over a two-year period employing periodic boundary conditions. Drift predictions are compared with the observed drift of three contemporaneous drifting stations with resonable agreement. The largest errors are found the observed drift of three contemporaneous drifting stations with reasonable agreement. The largest errors are found to occur in late summer, and may be due to nonsteady current effects. Boundary value calculations show that reduction of the shear viscosity (while still maintaining a large bulk viscosity) reduces the excessive stiffening often found in viscous models while still maintaining substantial changes in drift direction due to boundaries. Sensitivity studies show steady current effects to be small for drift rates over tens of days but not negligible for cumulative drift over years. drift over years

ICE CORES, DRILL CORE ANALYSIS, VOLCAN-IC ASH, ANTARCTICA—MARIE BYRD LAND. IC ASH, ANTARCTICA—MARIE BYRD LAND. Published petrographic descriptions of the volcanic sah bands in the Byrd Station deep drill core (Gow, 1971; E-10325, and Gow and Williamson, 1971; E-10462) have suggested some sources for sah among the volcanoes in Byrd Land and some possible climatic implications of this volcanism. The available petrographic and age data on volcanoes that are known to have crupted in Byrd Land in Quaternary time - Mt. Murphy, Toney Mountain, Mt. Takahe, and Mt. Wasche - suggest that Mt. Wasche and Mt. Takahe were the major sources of sah. Events recorded in the core occurred within the last 75,000 yr. The most distinctive petrographic characteristics of the Quaternary volcanic rocks are the abundance of olivine, plagicelase, and titansugite phenocrysts in the busslts, and of alkali feldspar and aegerine phenocrysts in the acid rocks.

MP 995 SUMMARY OF THE 1971 US TUNDRA BIOME PROGRAM.

Brown, J., International Biological Programme, Tundra biome; Proceedings IV. International Meeting on the Biological Productivity of Tundra, Leningrad USSR, October 1971. Edited by F.E. Wielgolaski and Th. Rosswall. Stockholm, Tundra Biome Steering Committee, April 1972, p.306-313.

RESEARCH PROJECTS, TUNDRA BIOME, UNITED STATES—ALASKA.

DNITED STATES—ALASKA.

Briefly outlined are the U.S. Tundra Biome studies including the interrelationships between tundra fauna and flora, photosynthesis, carbon dioxide budget, wet tundra soil science, and lake and pond eccepstems. Activities were centered primarily on the Barrow, Alaska area.

MP 996 INTERPRETATION OF THE TENSILE STRENGTH OF ICE UNDER TRIAXIAL STRESS.

Nevel, D.E., et al. International Conference on Port and Ocean Engineering Under Arctic Conditions, 3rd, Fairbanks, Aug. 11-13, 1975, Vol.1, University of Alaska, 1976, p.375-387, 12 refs. Haynes, F.D. 32-2219

ICE MECHANICS, ICE STRENGTH, TENSILE STRENGTH, STRESSES.

Oriffith, and later Babel, have previously developed a tensile fracture criterion for a two-dimensional state of stress. This theory is extended to the compression-compression region. From this theory the angle of fracture is developed. For uniaxial compression, the angle may be anywhere from 0 to 30 degrees measured from the direction of loading, depending upon the shape of the cavity. The theory is extended conceptually to three dimensions. Triaxial test data by Haynes for secondic are shown in this three dimensions! conceptually to three dimensions.

Haynes for snow-ice are shown in this three-dimensional fracture theory. The test data are slightly less than that predicted when the void in the snow-ice is spherical.

OXYGEN ISOTOPE PROFILES THROUGH THE ANTARCTIC AND GREENLAND ICE SHEETS.

STATION.

The Camp Century, Greenland, deep ice core reveals seasonal variations in the isotopic composition of the ice back to 8,300 y.b.p. This is not the case for the Byrd Station, Antarctica, deep ice core. Both cores show long-term perturbations in isotopic composition reflecting climatic changes from before the beginning of the last glaciation. But the complexity of the glaciology regime at Byrd Station precludes a rational choice of a time scale. Pole-to-pole correlations of the palasoclimatic data therefore become speculative except for the more pronounced features and general trends. general trends.

SEDIMENT TRANSPORT.
Physiognomic landscape features were used as geologic and vegetative indicators in preparation of a surficial geology, vegetation, and permafrost map at a scale of 1:1 million using ERTS-1 band 7 imagery. The detail from this map compared favorably with USGS maps at 1:250,000 scale. Physical boundaries mapped from ERTS-1 imagery in combination with ground truth obtained from existing small scale maps and other sources resulted in improved and more detailed maps of permafrost terrain and vegetation for the same area. BRTS-1 imagery provides for the first time, a means of monitoring the following regional estuarine processes: daily and periodic surface water circulation patterns, changes in the relative sediment load of rivers discharging into the inlet; and, several local patterns not recognized before, such as a clockwise back eddy offshore from Clam Gulch and a counterclockwise current north of the Forelands. Comparison of ERTS-1 and Mariner imagery has revealed that the thermokarst depressions found on the Alaskan North Slope and polygonal patterns on the Yukon River Delta Slope and polygonal patterns on the Yukon River Delta are possibly analogs to some Martian terrain features.

SEA ICE, ICE MODELS, I ICE MECHANICS.

Simulation results for sea ice drift, deformation and ice thickness variations in the Arctic Basin are presented using a dynamic-thermodynamic model which treats the ice as a rigid plastic continuum. Using available observed atmo-spheric and oceanic forcing data, numerical model simulations spheric and oceanic forcing data, numerical model simulations are made over a four year long period employing one day time steps in a finite difference code with a resolution of 125km. Drift, deformation, stress and ice thickness time series from the simulation results in the near shore region off the Alsakam and Canadian North slope are reported and briefly examined in light of available observations.

DIELECTRIC CONSTANT AND REFLECTION COEFFICIENT OF THE SNOW SURFACE AND NEAR-SURFACE INTERNAL LAYERS IN THE MCMURDO ICE SHELF.

—MCMURDO ICE SHELF.

An impulse radar system was used to profile the shape and lateral extent of the brine layer in the McMurdo Ice Shelf.

A small antenna was also used to determine if reflective layers could be detected in the upper 5 m of snow. The radiated impulse center frequency was 626 magahertz with an estimated frequency spectrum of 375 and 875 at the -3 de... act points. The measurement technique is described. The study indicates that layers of dielectric discontinuity can be detected at shallow depths in point snow. The shallow depth at which the internal layers were detected suggests that they represent density variations in the snow, perhaps associated with summer melt features less than 5 mm thick.

NEERING, SNOW CRYSTALS, SNOWFALL, BLOWING SNOW.

The general properties of snow are described with a view to engineering applications of data. Following an introduction and a short note on the origins of snow, data are given for fall velocities of snow particles, and for mass flux and particle concentrations in falling snow and blowing snow. Notes on the structural properties of deposited snow cover grain size, grain bonds, bulk density, overburden pressure, and permeability. A section on impurities deals with stable and radioactive isotopes, chemical impurities, insoluble particles, living organisms, actidity, and gases. Mechanical properties are treated only selectively, and the reader is referred to another paper for comprehensive coverage. The selective treatment deals with stress waves and strain waves, compressibility, effects of volumetric strain on deviatoric strain, and specific energy for comminution. The section on thermal properties covers heat capacity, latent heat, conductivity, diffusivity, heat transfer by vapor diffusion, heat transfer snd vapor transport with forced convection, and thermal strain. The section on electrical properties of see, and proceeds to a summary of the dielectric properties of ice, and proceeds to a summary of the dielectric properties of ice, and proceeds to a summary of the dielectric properties of snow, including dielectric dispersion, permittivity, dielectric lose, and d.c. conductivity. There are also notes on the thermoelectric effect and c.n electrical charges in falling and blowing snow. The section on optical properties deals with transmission and attenuation of visible radiation, with spectral reflectance, and with long-wave emissivity. The review concludes with some comments on engineering problems that involve snow, and the requirements for research and development. (Auth.)

STRUCTURES IN ICE INFESTED WATER. Assur, A., 1972, [Vol.2], Symposium on Ice and its Action on Hydraulic Structures, 2nd, Leningrad, Sept. 26-29, 1972. Papers, p.93-97, 7 refs.

28-3899 ICE LOADS, OFFSHORE STRUCTURES, ICE PRESSURE, ICE MODELS.

PRESSURE, ICE MODELS.

A method is presented to calculate the effective ice load on vertical structures depending upon width of structure related to ice thickness and fundamental ice properties (enisotropic semirestrained crushing strength, Young's modulus, Possoo's ratio, internal friction). The besic equation satisfies the theoretical identation solution for a straight wall. Both extremes appear as simple intercepts on a plot which futhermore can be linearized. The concept is compared with largely Russian test material and equations which show good agreement. Internal friction must be considered in the analysis since it increases possible ice forces. Due to this local identation forces by ice can be higher as previously assumed for the design of ships.

Buckling instability introduced complications in nucled tests. For structures in the field the random configuration of ice collars must be considered. For this a complete solution is still not available.

MP 1022 CLASSIFICATION AND VARIATION OF SEA ICE RIDGING IN THE ARCTIC BASIN. Hibler, W.D., III, et al, AIDJEX bulletin, Jan. 1974, No.23, p.127-146, 16 refs. Mock, S.J., Tucker, W.B.

28-4069 SEA ICE, ICE STRUCTURE, ICE PRESSURE, ICE MODELS, PRESSURE RIDGES.

MODBLS, PRESSURE RIDGES.

A one-parameter model for pressure ridges is developed and compared with good agreement to more than 3000 km of leser profile data taken from November 1970 to February 1973 in the Arctic basin. Using a parameter called ridging intensity, which may be determined for a region from the mean number of ridges per unit length and the mean ridge height, the number of ridges per kilometer at any height level may be predicted. Results from a study of regional and temporal variation in ridging indicate that although magnitudes of ridging intensity vary in time, the relative regional variations are similar. Consequently, three distinct regions of ridging intensity thaving relatively stable boundaries can be defined. Annual variation in new ice production due to ridging is sufficiently large to suggest that ridging plays an important role in the overall mass balance of the Arctic basin.

MP 1023

SALINITY VARIATIONS IN SEA ICE.

Coy, G.F.N., et al. Journal of glaciology, 1974, 13(67), p.109-122, In Bnglish with French and German summaries. 3 refs. Weeks, W.F.

SEA ICE, CHEMICAL ANALYSIS, SALINITY, ICE COVER THICKNESS.

ICE COVER THICKNESS.

The salinity distribution in multi-year sea ice is dependent on the ice topography and cannot be adequately represented by a single average profile. The cores collected from areas beneath surface humnocks generally showed a systematic increase in salinity with depth from 0 per mille at the surface to about 4 per mille at the base. The cores collected from areas beneath surface depressions were much more saline and displayed lerge salinity fluctuations. Salinity observations from sea ice of varying thicknesses and age collected at various Arctic and sub-Antarctic locations revealed a strong correlation between the average as alinity of collected at various Arctic and sub-Antarctic locations revealed a strong correlation between the average salinity of the ice S and the ice thickness h. For salinity samples collected from cold sea ice at the end of the growth season, this relationship can be represented by two linear equations: S = 14.24 - 19.39 h (h < 0.4 m); S = 7.88 - 1.59 h (h > 0.4 m). It is suggested that the pronounced break in slope at 0.4 m is due to a change in the dominant brine drainage mechanism from brine expulsion to gravity drainage. A linear regression for the data collected during the melt season gives S = 1.58 + 0.18 h. An annual cyclic variation of the mean salinity exists for multi-year ses ice. The mean salinity reaches a maximum at the end of the growth season and a minimum at the end of the melt season.

ICE PORCES ON VERTICAL PILES.

Nevel, D.E., et al, U.S. Army Science Conference, West Point, N.Y., June 20-23, 1972. Proceedings. Vol. III, Washington, D.C., U.S. Army Research and Development Office, 1972, p.104-114, AD-750 358, 16 refs.

Perham, R.E., Hogue, G.B. 29-121

SEA ICE, ICE PRESSURE, PILE STRUCTURES. The force that floating ice sheets can exert on vertical piles is important to the design of both military and civilian structures. Present design codes call for 400 psi as the crushing strength of ice without regard to the influencing factors and their variation. The forces which drive the ice into the structure can be water currents, wind, or thermal expansion. These driving forces may be large enough to cause the ice to fail at or near the surface. The

purpose of this research is to define this limiting force level and gain a better understanding of the failure process in the ice. (Auth.)

WATER PERCOLATION THROUGH HOMO-

GENEOUS SNOW.

Colbeck, S.C., et al, The role of snow and ice in hydrology; proceedings of the Banff Symposia, Sept. 1972, Vol.1, Geneva, Switzerland, WMO-IAHS, Unesco, 1973, p.242-257, With French summary. 7 refs. Includes discussions.

Davidson, G. 29-211

SNOW WATER CONTENT, SNOWMELT, SNOW COVER STRUCTURE, SNOW PERMEABILITY.

COVER STRUCTURE, SNOW PERMEABILITY.
The gravity flow theory of water percolation through snow
is generalized to include any power law relationship between
permeability to the water phase and effective water saturation.
Experimental observations of water percolation through homogeneous snow are described. It is found that the exponent
in the power law is about 3 for homogeneous snow. The
theory is used to construct diurnal meltwater waves and
those compare favorably with the observed waves. The
differences between the results found for natural snow and
those found for repacked snow are discussed. The lower
limit of applicability of the gravity flow theory is uncertain.

SEASONAL REGIME AND HYDROLOGICAL SIGNIFICANCE OF STREAM ICINGS IN CEN-TRAL ALASKA.

Kane, D.L., et al, The role of snow and ice in hydrology; proceedings of the Banff Symposia, Sept. 1972, Vol.1, Geneva, Switzerland, WMO-IAHS, Unesco, 1973, p. 528-540, With French summary. 16 refs. Includes discussions.

Slaughter, C.W. 29-232

RIVER ICE, FREEZEUP, ICE FORMATION, AERIAL PHOTOGRAPHY, METEOROLOGICAL FACTORS, HYDROLOGIC CYCLE.

FACTORS, HYDROLOGIC CYCLE.

Many streams in Arctic and sub-Arctic regions are characterized by accumulations of ice in the channel and nearby floodplain during the winter months. Field data on the rates of growth of this icing and on various climatic factors has been collected at a small research watershed near Fairbanks, Alaska. The volume of icing growths is estimated from aerial photographs. Hydrologic implications are derived by comparing the volume of these icings with other elements of the hydrologic cycle. Discussion on how the hydrologic cycle is modified by these ice accumulations is also included.

MEASURING THE UNIAXIAL COMPRESSIVE

MEASURING THE UNIAXIAL COMPRESSIVE STRENGTH OF ICE. Haynes, F.D., et al, Journal of glaciology, 1977, 19(81), p.213-223, In English with French and German summaries. 7 refs.

Mellor, M. 32-2445

COMPRESSION, COMPRESSIVE STRENGTH, ICE STRENGTH, SHEAR STRESS, ICE CRYSTALS, MEASURING INSTRUMENTS. SIRENGIH, ICE STRENGIH, SHEAR STRESS, ARE STRESS, ARE STRESS, MEASURING INSTRUMENTS. An attempt was made to develop a simple but accurate method for making compressive strength tests on right circular cylinders. Compliant loading platens were designed to apply uniform normal stress without introducing significant interface radial shear stresses. The compliant platens gave reproducible results that agree well with results obtained by a precise conventional technique. Accurate results were obtained with simple specimen preparation, and with short specimens where the length-to-diameter ratio was less than unity. Platens were made from a rubber-like uretianse which was molded in aluminum cylinders to provide lateral ventraint. Uniaxial compression tests on cylindrical polycrystalline ice specimens were made to determine the characteristics of the platens. For 21 specimens with ends prepared on a lapping plate to obtain a mirror finish, the measured strength showed a variation of only 13% for length-to-diameter ratios from 0.74 to 2.5, with no systematic trend. Another 21 specimens with length-to-diameter ratios of about 2.35 were tested with various platens and various methods of specimen end preparation. The strength for specimens with saw-cut ends and for those with ends lapped showed very little difference when tested with the rubber platens.

INVESTIGATION OF AUTOMATIC DATA COL-LECTION EQUIPMENT FOR OCEANOGRAPH-IC APPLICATIONS.

Dean, A.M., Jr., International Conference on Port and Ocean Engineering Under Arctic Conditions, 4th, St. John's, Sept. 26-30, 1977, Vol.2, Memorial University of Newfoundland, 1978, p.1111-1121, 13 refs. 32-2407

REMOTE SENSING, MONITORS, OCEANOG-RAPHY, DATA PROCESSING, METEOROLOGI-CAL DATA.

This paper deals with the instrumentation requirements for in-situ monitoring of specified factors in open water. It contains application information suitable for an organization initiating or extending an oceanographic data collection pro-

gram. The analysis includes an investigation and evaluation of sensing methodology, sensors, monitoring equipment, an available data collection systems. A comparison of available equipment for a first-year effort is presented.

MESOSCALE MEASUREMENT OF SNOW-COVER PROPERTIES.

Bilello, M.A., et al, The role of snow and ice in hydrology; proceedings of the Banff Symposia, Sept. 1972, Vol.1, Geneva, Switzerland, WMO-IAHS, Unesco, 1973, p.624-643, With French summary. 16

Bates, R.E., Riley, J.

SNOW DEPTH, SNOW DENSITY, METEORO-LOGICAL FACTORS, SNOW TEMPERATURE.

LOGICAL FACTORS, SNOW TEMPERATURE. Physical characteristics of the snow cover and associated meteorological conditions were observed at nineteen sites in and around Fort Greely, Alaska, during the winter of 1966-67. Saowhill totaled 245 cm and maximum snow depths of 80 to 100 cm were observed in a major portion of Fort Greely. Measurements at nine sites showed the snow density to be light; for example, the average density in the forest was less than 0.24 g/cc. However, exceptions could be expected as observed at Jarvis Creek, where the density averaged 0.33 g/cc. Daily temperature measurements made within the snow pack also showed that the anow in the forest was colder than that at exposed sites. Associations between snow cover properties and weather were tested and the results substantiated previous studies, which showed good relationships between seasonal snow cover density and windspeed/air temperatures.

SEA ICE, ICE MECHANICS, ICE STRUCTURE, DRIFT, METEOROLOGICAL FACTORS.

DRIFT, METEOROLOGICAL FACTORS.
The atmospheric circulation which occurred during the Bering Sea Experiment, 15 February to 10 March 1973, in and around the experiment area is analyzed and related to the macroscale morphology and dynamics of the sea ice cover. The ice cover was very complex in structure, being made up of five ice types, and underwent strong dynamic activity. Synoptic analyses show that an optimum variety of weather altuations occurred during the experiment: an initial strong anticyclonic period (6 days), followed by a period of strong cyclonic activity (6 days), followed by a period of strong cyclonic activity (4 days). The data of the mesoncale test areas observed on the four sea ice option flights, and ship weather, and drift data give a detailed description of mesoscale lost dynamics which correlates well with the macroscale view: anticyclonic activity advects the ice southward with strong ice divergence and a regular lead and polynya pattern; cyclonic activity advects the ice northward with ice convergence, or slight divergence, and a random lead and polynya pattern. LAKE ICE, EXPLOSION EFFECTS, ICE BREAK-

CARE ICE, EXPLOSION EFFECTS, ICE BREAK-UP.

Operation BREAKUP, FY 66, was a series of small, single and row charge, chemical explosive detonations fired in fresh water to crater the overlying sheet ice. The experiments were conducted in the winter of 1966 under three feet of ice at Blair Lake, 33 miles SSE of Fairbanks, Alaska. The operation had the following purposes:

(1) to determine the cratering effects of single and row charges detonated below an ice layer; (2) to study bubble coalescence; and (3) to support theoretical studies of cratering physics. Technical programs included crater measurements, ice surface motion, engineering properties, and fish surveys. Some results and conclusions were:

(1) the relationship between depth of detonation and ice crater radius has been defined for 136 pound C4 spherical charges for various experimental conditions; (2) shock wave reflection from the lake bottom did not appear to enhance the crater dimensions; (3) row charge crater dimensions were defined for three charge spacines; (4) cracks appeared to propagate better from larger yield explosions under ice of the same thickness; (5) there did not appear to be any evidence of bubble coalescence in the experiments; (6) commonly used scaling laws may be used to estimate the effects of higher yield ice creating explosions; (7) the procedures used are adaptable to civil application; (8) a detailed evaluation was made of the effects of under-ice explosions on fish; and (9) maintenance of open water gaps created by explosions is affected by refereing applications of the BREAKUP results are included.

TESTS.

The Iowa Institute of Hydraulic Research has undertaken model studies on the investigation of ice forces on vertical piles. Model techniques for the study of ice-breaking phenomena have been developed, and the similarity between the model indications and prototype conditions has been demonstrated. Tests on the relationships between ice forces (ice strength) and pile diameter, ice thickness, and relative velocity (strain rate) between ice and structure have been completed. The experimental results were satisfactorily explained by a theoretical approach, and the combination of these relationships led to a basic empirical formula for the calculation of the maximum penetration strength for a circular pile, which agrees with available field measurements and also in part with model investigations in Russia. The suggested formula was modified for application to different structural shapes and degree of contact between ice and structure as well as for application to the indentation case of pile-ice interaction.

SHELF.
The author comments on the continued existence of the apparently unstable West Antarctic Ice Sheet and Ross Ice Shelf.
The new field data on the Ross Ice Shelf and fast moving ice streams obtained by G. Robin (29-3125 or F-14813) is considered essential to the future solution of this geophysical puzzle. It is possible that the West Antarctic Ice Sheet is indeed disintegrating as suggested by T. Hughes (29-0067 or F-12956). A more accurate answer to this question should be obtainable from a three dimensional glacier mechanics analysis carried out with the aid of computer calculations or with field observations. It is hoped that Robin's data on ice streams may also help to solve the problem of why fast moving ice streams form near the edge of the West Antarctic Ice Sheet.

The soils of the national Tundra Biome sites, which include subantarctic locations, reflect a significantly wide range of soil-forming factors and conditions. It is the purpose of this report to present the most representative set or sets of soil data available for each national project. Presentation of data is confined to the upper three to four soil layers or horizons since these are the most biologically significant for purposes of this volume and other Tundra Biome synthesis activities. The main emphasis here is to provide physical, chemical and thermal soils properties which supplement data presented elsewhere in this volume and which are required for subsequent interpretations of those reports. A brief summary of major soil conditions at each site is given in order to provide the uninitiated reader with a cursory understanding of the soil physical environment.

30-1270 RIVER FLOW, SEDIMENTS, PERMAFROST DIS-TRIBUTION, SNOW COVER, RIVER ICE, SEA ICE, MAPPING, REMOTE SENSING, ERTS IM-AGERY.

AGERY.

The author has identified the following significant results. ERTS-1 imagery provides a means of distinguishing and monitoring estuarine surface water circulation patterns and changes in the relative sediment load of discharging rivers on a regional basis. Physical boundaries mapped from ERTS-1 imagery in combination with ground truth obtained from existing small scale maps and other sources resulted in improved and more detailed maps of permafrost terrain and vegetation for the same area. Snowpack cover within a research watershed has been analyzed and compared to ground data. Large river icings along the proposed Alaska pipeline route from Prudhoe Bay to the Brooks Range have been monitored. Sea ice deformation and drift northeast of Point Barrow, Alaska have been measured during a four

day period in March and shore-flat ice accumulation and ablation along the west coast of Alaska have been mapped for the spring and early summer seasons. MP 1048

THICKNESS, RADIO WAVES.

New results about ground conductivity in North America became available from geophysical studies near Fairbenks, from sites along the Alsaka Pipeline and in several areas of the Canadian Arctic; at these locations ground and/or arrorne conductivity measurements were made by measuring the wavetilt and/or the surface impedance of radio ground-waves. The results showed that the ground conductivity in permafrost areas of North America is very heterogeneous, so that it is not directly apparent how to assign an effective conductivity value to a path of practical length (approx. 100 km). The geological and permafrost conductions vary much in Alsaka, so that measurements at a location are representative of a small area only, leaving large areas of Alsaka open to question. Theoretical evaluations of the seasonal changes in ground conductivity and their effect on radiowave propagation and electrical grounding are also discussed.

ICE.

On several field projects in Greenland, Antarctica and the Swiss Alps, the extraction technique of traces from several tons of ice has been developed and perfected. The procedures are as follows. Surface ice samples are melted in vacuum melt vessels, whereas in bore holes the ice is melted in situ under vacuum at the desired depth. Until now the maximum depth from which samples have been extracted is 780 m. The gases escaping during the melting process are pumped through a molecular sieve for drying and collection of CO2. The remaining gases are compressed for further treatment in the laboratory. Soluble chemistry may be carried out either on the melt water pumped to the surface (collection of Si) or down hole by circulating the melt water through ion exchange resins (collection of CO2). The melt water can be filtered for the collection of CO2. Ar and Si samples can be obtained for radioisotopic dating. The results of the Si-32 samples allow us to establish an apparent helf-life for \$1.32 dating. The possible causes of the C-14 variations are discussed and ways to solve the problem suggested. (Auth.)

ECOLOGICAL INVESTIGATIONS OF THE TUNDRA BIOME IN THE PRUDHOE BAY RE-GION, ALASKA

which was stationed primarily out of Barrow, performed a series of environmental and terrestrial ecological studies at Prudhoe Ray. This volume reports specifically on the Prudhoe results and is divided into three major subdivisions: (1) abiotic and soil investigations, (2) plant investigations, and (3) animal investigations. The abiotic section contains papers on the air and soil temperature regimes; the snow cover, particularly its properties adjacent to the roadnet; major soil and landform associations, and the chemical composition of soils, runoff, lakes, and rivers. The plant section contains reports on a general vegetation survey; a following vegetation mapping project, and a study of the growth of arctic, boreal, and alpine biotypes in an experimental transplant garden. The animal section contains reports on the tundra invertebrates; the bird, lemming, and for populations, and the behavioral and physiological investigations of caribou and several experimental reindeer. Appendices contain a checklist of the vascular, bryophyte, and lichen flors of the Prudhoe Bay area and selected data on vegetation. Several of the papers draw comparisons with the Barrow tundra. The volume includes a considerable number of tables in its attempt to document for the first time the abiotic, flora, and fauna of this relatively unknown arctic tundra landscape.

MENTS, LANDSAT.

The LANDSAT Data Collection System (DCS) provides the capability of rapidly collecting hydrologic, meteorologic and environmental data at remote sites throughout the United States and Canada. The coded signals are transmitted via satellite to NASA ground receiving stations where the data are compiled and teletyped to the user. The number of transmissions per day varies considerably depending on the location of each data collection platform (DCP). During the past two years, many sensors have been interfaced to the DCP; one of the most important is a porous cup tensiometer constructed so that a transducer provides a continuous reading of pore water pressure. Field tests have shown that the transmissions from the DCP are accurate and reliable. This system appears to provide a reliable means of measuring pore water pressure at freeze-up and thaw, critical data needed for validation of current hydrologic models.

ICE SHEETS, GLACIER OSCILLATION, ICE SHELVES, SEA LEVEL.

SHELVES, SEA LEVEL.
Giaciology's grand unsolved problem, or set of interrelated problems, concerns the West Antarctic Ice Sheet: how it formed, whether it it growing or diaintegrating, why fast moving ice streams form at its periphery, etc. Geological evidence indicates that before 10,000 yr ago the West Antarctic Ice Sheet was much larger, covering the area, now below sea level, presently occupied by the Rosa Ice Shelf and that a large scale retreat took place at its edge. The retreat was probably caused by the large rise in sea level that occurred when the ice sheets in the northern hemisphere melted at the end of the last ice age. It has been suggested that the West Antarctic Ice Sheet is still disintegrating, its edge retreating where it joins the Rosa Ice Shelf on the order of 70 m/yr. This slowly occurring destruction could account for the present rate of rise of the mean sea level. Recent data collected on the Rosa Ice Shelf reaches the startling conclusion that the position of the edge of the ice sheet at least at one location is advancing

at the very fast rate of 1 km/yr. Extensive field data will be required to determine whether the ice sheet is disintegrating or growing and at what rate.

30-3888

SEA ICE, DRIFT, ICE DEFORMATION, POSI-TION (LOCATION), LANDSAT.

TION (LOCATION), LANDSAT.

A semi-automatic procedure is described for transferring ice coordinates rapidly and accurately from one LANDSAT image to another and for simultaneously estimating all linear measures of the ice deformation. The procedure takes into account the non-parallel nature of the longitude lines and the finite curvature of the latitude lines, factors which are particularly critical in the polar regions. Necessary inputs are the location coordinates (latitude and longitude) of the center of each image and the location of two arbitrary points on a line of longitude on the image. These equations, which are valid over distances of several hundred kilometers, bypass the complex and time-consuming procedure of projecting points on the spheroid. After the transfer of common ice feature locations (on successive days) is completed, a least-squares program yields the average strain rate and vorticity, with the strain rate being independent of errors in the transfer of the coordinate system. Transfer, vorticity, and strain rate errors of the technique are described.

32-2447 FLOATING ICE, ICE BEARING CAPACITY, TENSILE STRESS, ICE ELASTICITY, LOADS (FORCES), ICE COVER THICKNESS, MATHEMATICAL MODELS.

FORCES), ICE COVER INICANESS, MATHEMATICAL MODELS.

The safe bearing capacity of a floating ice sheet is usually determined by limiting the maximum tensile stress which occurs under the load at the bottom of the ice sheet. If the size of the load distribution is large compared to the ice thickness, the thin plate theory predicts these stresses correctly. However, if the size of the load distribution becomes small compared to the ice thickness, the plate theory overestimates the stresses. In this case the ice sheet should be treated as a three-dimensional elastic layer problem for loads distributed over a circular area, and have limited the results to the atress at the bottom of the ice sheet directly under the center of the load. In the present paper the stresses are evaluated at any radial position, and it is shown how these stresses approach those for the plate theory as the radial position becomes large. The solutions for the stresses are presented in integral form, as well as graphs from the numerical integration. These new results are significant for the superposition of stresses when two concentrated loads act near each other. Similarly for loads distributed over a rectangular area, the plate theory will overestimate the stresses if the dimensions of the load become small compared to the ice thickness. For this case integral solutions are presented for the stresses, and are evaluated directly under the center of the load. (Auth.)

PLEXURAL STRENGTH OF ICE ON TEMPER-ATE LAKES.

Gow, A.J., Journal of glaciology, 1977, 19(81), p.247-256, In English with French and German summaries. 7 refs. 32-2448

FLEXURAL STRENGTH, LAKE ICE, ICE CRYS-STRUCTURE, TENSILE STRESS, ICE CRACKS, TESTS.

Large, simply supported beams of temperate lake ice generally yield significantly higher flexural strengths than the same beams tested in the cantilever mode.

Data support the view that a significant stress concentration may exist at the fixed corners of the cantilever beams.

Maximum effects the fixed corners of the cantilever beams. Maximum effects are experienced with beams of cold, brittle ice substantially free of structural imperfections; the stress concentration factor may exceed 2.0 in this kind of ice. In ice that has undergone extensive thermal degradation the stress concentration effect may be eliminated entirely. Simply supported beams generally test stronger when the top surface is placed in tension. This behavior is attributed to differences in ice type; the fine-grained, crack-free top layer of snow-ice usually reacting more strongly in tension than the coarse-grained bottom lake ice which is prone to cracking. DE-ICING OF RADOMES AND LOCK WALLS USING PNEUMATIC DEVICES.

Ackley, S.F., et al, Journal of glaciology, 1977, 19(81), p.467-478, In English with French and German sum-

maries. 1 ref. Itagaki, K., Frank, M.

ICE REMOVAL, PNEUMATIC EQUIPMENT, ICE DETECTION, ICE NAVIGATION.

ICE REMOVAL, PNEUMATIC EQUIPMENT, ICE DETECTION, ICE NAVIGATION.

A rough comparison between thermal and mechanical methods of de-icing indicates that mechanical methods could potentially de-ice with an order-of-magnitude less energy than that required to melt an ice accretion. Two applications of mechanical de-icing using pneumatically driven inflatable described in this report. The first of these was the de-icing of a small cylindrical radome used for air navigational purposes. Two seasons of testing were conducted with a de-icer consisting of an inflatable-deflatable flexible plastic covering. The de-icer was driven by tanks with a de-icer consisting of an inflatable-deflatable flexible plastic covering. The de-icer was driven by tanks with the de-icer consisting of an inflatable-deflatable flexible plastic covering. The selecting that were recharged by an on-site air compressor in response to a pressure sensor. The de-icing cycle was activated by an ice detector so the system responded to icing events on a demand basis driven by the ice detector. The system proved successful in keeping the radome free of ice without manned operation and with small energy consumption in a mountain icing environment. The second application was an attempt to de-ice the walls of locks used in river navigational facilities. Ice usually formed at the high-water-first by the freezing of the water exposed to low air temperatures or by the pressing of ice against the walls by alips using the locks. The de-icers consisted of air-driven hoses mounted on the wall covered by a thick flexible rubber mat and protected from ship damage by steel outer plates. This method was successful in removing ice accumulations up to 2 m long by 0.3 n thick over the area covered by the de-icer against abrasion by ships may make this de-icing method prohibitively expensive compared with meth-

ods which are not as susceptible to damage by ships (e.g., chemical coating and electrical heating cables buried in the walls).

ICE SHELVES, ICE STRUCTURE, ICE MECHANICS, ICE FRICTION, ICE THERMAL PROPERTIES, ICE (CONSTRUCTION MATERIAL), ENGINEER-ING, SEA ICE, ICE STRENGTH.

ING, SEA ICE, ICE STRENGTH.

As the continental sherves of the Arctic become important as source areas for the oil and minerals required by human society, sea ice becomes an increasing challenge to engineers. The present paper starts with a consideration of the different fields of engineering which require information on sea ice with the tasks ranging from the design of ice-breaking ships to Arctic drilling platforms and man-made ice islands. Then the structure of sea ice is described as it influences the observed variations in physical properties. Next the status of our knowledge of the physical properties important to engineering is reviewed. Properties discussed include mechanical properties (compressive, tensile, shear and flexural strengths; dynamic and static elastic moduli; Poisson's ratio), friction and adhesion, thermal properties (specific and latent heats, thermal conductivity and diffusivity, density) and finally electromagnetic properties (dielectric permittivity and loss, resistivity). Particular attention is given to parameters such as temperature, strain-rate, brine volume, and loading direction as they affect property variations. Gaps, contradictions in the data, and inadequacies in testing techniques are pointed out. Pinally suggestions are made for future research, especially for more basic laboratory studies designed to provide the data base upon which further theoretical developments as well as field studies can be built. ERS, SEA ICE, ICE CONDITIONS, UNITED STATES—ALASKA—PRUDHOE BAY.

During March-May 1976, a combination of laser and radar ranging systems was used to study the motion of both the fast ice and the pack ice near Narwahl and Cross Islands, two barrier islands located 16 and 21 km offshore in the vicinity of Prudhoe Bay, Alaska. Laser measurements of targets on the fast ice near Narwahl laland indicate small net displacements of approximately 1 m over the period of study (71 d) with short-term displacements of up to 40 cm occurring over 3 d periods. The main motion was outward normal to the coast and was believed to be the result of thermal expansion c? the ice. The radar records of fast-ice sites farther offshore show a systematic increase in the standard deviation of the displacements as measured parallel to the coast, reaching a value of 6.6 m at 31 km. The farthest fast-ice sites show short-term displacements of up to 12 m. There are also trends in the records that are believed to be the result of the general warming of the fast ice with time. Radar targets located on the pack ice showed large short-term displacements (up to 2.7 km) but negligible net ice drift along the coast. There was no significant correlation between the movement of the pack and the local wind, suggesting that coastal ice prediction models can only succeed if handled as part of a regional model which incorporates stress transfer through the pack. The apparent fast-ice-pack-ice boundary in the study are was located in 30-35 m of water. (Auth.)

MP 1067 SHORT-TERM FORECASTING OF WATER RUN-OFF FROM SNOW AND ICE. Colbeck, S.C., Journal of glaciology, 1977, 19(81), p.571-588, In English with French and German sum-maries. Refs. p.585-587. 32-2474

RUNOFF FORECASTING, SNOW HYDROLOGY, ICE MELTING, SNOW MELTING, GLACIAL HYDROLOGY, MELTWATER, SNOW
COVER EFFECTS, MODELS.

COVER EFFECTS, MODELS.

Accurate forecasting of water run-off from snow covers and glaciers is increasingly important because of the increasing competition for scarce water resources. The trend toward conceptual computerized models of hydrologic systems requires extensive knowledge of the physical aspects of those systems. Unlike river and stream networks, the hydrological characteristics of snow covers and glaciers are highly variable with time and cannot be easily defined. After reviewing the physical aspects of water flow through snow covers and glaciers, it is concluded that snow covers and glaciers

are predictable hydrological systems once the melt metamorphism of the snow is complete and the englacial conduits have been established.

However, much additional information about snow and ice masses must be generated before general forecasting techniques can be established for all situations. (Auth.)

ROLE OF RESEARCH IN DEVELOPING SUR-FACE PROTECTION MEASURES FOR THE ARCTIC SLOPE OF ALASKA.

John on, P.R., Symposium on Surface Protection through Prevention of Damage (Surface Management). Focus: the Arctic Slope, Anchorage, Alaska, May 17-20, 1977. Proceedings. Edited by M.N. Bvans. Anchorage, Alaska, Bureau of Land Management, Mar. 1978, p.202-205. 32-2648

ENVIRONMENTAL PROTECTION, SNOW AC CUMULATION, SNOW (CONSTRUCTION MATERIAL), ICE (CONSTRUCTION MATERIAL), CIVIL ENGINEERING, U.S. ARMY CRREL, RESEARCH PROJECTS, ALASKA—NORTH SLOPE. UNITED STATES

The U.S. Army Cold Regions Research and Engineering Laboratory (USA CRREL) has long conducted research in snow, ice, and permatrost. It also translates foreign language engineering papers and publishes research reports, monographs, and bibliographies. Snow and ice roads and construction sand bibliographies. Sand so wand ice roads and construction pads have been used, primarily on the Arctic Slope, during the last few winters. Some have been used, charing the last few winters. Some have been used, during the last few winters. Some have been successful but problems exist which will require further experience and research to solve. One problem is that of snow supply. Snowfall on the Arctic Slope is limited, particularly early in the season when it is most desired. Few good data are available on total quantities and the time pattern of snowfall but Wyoming Snow Gages, now being installed by a number of government agencies and private organizations, are beginning to provide some data which can be used with some confidence. The snow which falls is often blown off by the strong winds which are common in the area so it is not available where it is needed. Research is under way on equipment and techniques for collecting snow and inducing drifting.

FLOATING ICE, REMOTE SENSING, SENSOR MAPPING, AERIAL RECONNAISSANCE, SEASONAL VARIATIONS.

SONAL VARIATIONS.

The current increase of scientific interest in all forms of floating ico-sea ice, lake ice, river ice, ice abelves and icebergs—has occurred during a time of rapid evolution of both remote-sensing platforms and sensors. The application of these new research tools to ice studies in the Arctic and Antarctic has generally been both piecemeel and sporadic, partly because the community of ice scientists has not kept up with the rapid advances in remote sensing technology and partly because they have not made their needs known to the space community.

This paper seeks to help remody the latter shortcoming. The remote sensing requirements for floating ice studies are given, and the capabilities of various existing and future sensors and sensor combinations in meeting these requirements are discussed. The desirable future sensors are also discussed from both the research and operational points of view.

DYNAMICS OF SNOW AVALANCHES.

Mellor, M., Rockslides and avalanches, 1. Natural phenomena. Edited by B. Voight, New York, Elsevier, 1978, p.753-792, 22 refs.

32-2937

AVALANCHE MECHANICS, SNOW COVER STABILITY, SHEAR STRAIN, AVALANCHE

WIND.

After a general introduction to snow avalanches and their consequences, type classification is discussed, and classification schemes are described briefly. The first technical section deals with deformation and displacement of snow slopes prior to avalanche release, with the failure process, and with the propagation of initial failure. The following section describes various types of avalanche motion after release. Representative values are suggested for slope angles, initial accelerations, flow density, driving stresses, and travel velocities. The third technical section considers idealized theoretical analyses of avalanche motion. The final technical section covers the dynamic forces imposed by snow avalanches and their associated "winds." Measured values of impact stresses are summarized, and direct impact stresses for "wide" avalanches are deduced from simple theory. Porces induced by interfacial shear and avalanche deflection are considered by interfacial shear and avalanche deflection are considered by interfacial shear and avalanche winds, or "air blast," are discussed. In the conclusion there is a simplified tabulation of representative values for stress ranges, typical strain rates and typical velocities in the various avalanche processes.

IN-SITU MEASUREMENTS ON THE CONDUC-TIVITY AND SURFACE IMPEDANCE OF SEA-ICE AT VLF PREQUENCIES.

McNeill, D., et al. Copenhagen. Polyteknisk laerean-stalt. Laboratoriet for elektromagnetisk feltteori. Report, Dec. 1971, R105, 19p. plus diagrams, 9 refs. Also published in Radio science, Jan. 1973, 8(1):23-30. Hoekstra, P.

ICE, ICE RESISTIVITY, ELECTRICAL SEA RESISTIVITY.

RESISTIVITY.

An experimental program to measure in-situ values of the electrical conductivity and surface impedance of sea ice at VLF frequencies was carried out at Pt. Barrow, Alaska. Temperature, salinity, and resistivity were measured as a function of depth in the ice for both first year and multi-year sea ice by means of cored samples. All three quantities varied with the age of the ice and, in addition, the resistivity varied with age from 100 to 10,000 ohm-meters at the sea water interface. The wave tilt of a VLF plane wave propagating over sea ice is theoretically linearly dependent on the thickness. Measurements of the quadrature phase wave tilt at 18.6 KHz give values of the right order of magnitude but erratic in local behavior. Short-spacing Wenner array resistivity measurements and telluric current measurements at VLF demonstrated that the erratic behavior was due to significant horizontal variations of the aea ice resistivity over distances of a few feet.

SUBSEA PERMAFROST, PERMAFROST PHY-SICS, PERMAFROST DISTRIBUTION, ENGI-NEERING.

The overall objectives of the CRREL participation in the subsea permatrost program are to quantify the engineering characteristics and sacertain the distribution of permatrost beneath the Beautort Sea and to determine their relationship beneath the Beaufort Sea and to determine their relationship to temperature, sediment type, ice content and chemical composition. Permafrost was present in the four boles drilled at Prudhoe Bay. Ice-bonded permafrost was absent in the upper 30 meters of sediment up to 17 kilometers from shore. Based on negative temperature gradients and pore water chemistry, ice-bonded permafrost should be encountered at 30- and 43-meter depths at sites PB-2 and PB-3, respectively. It appears that the depth to the ice-bonded permafrost decreases with increasing distance from shore and depth of water. Highly over-consolidated marine clays were encountered seaward of Reindeer Island. The overconsolidation probably resulted from the freeze-thaw history. The presence of these stiff, marine clay deposits is an important consideration for stiing structures associated with offshore developments.

ENVIRONMENTAL IMPACT, ICE SHELVES, DRILLING, RESEARCH PROJECTS, ANIARC-TICA—ROSS ICE SHELF.

The acientific objectives of the Ross Ice Shelf Project (RISP) are to drill into the ice shelf to investigate the physical, chemical, biological, and geological conditions in the ice shelf, the water mass beneath the ice, and the soft sediments and bedrock at the bottom of the sea, and to use the data obtained for interpretation of the present conditions and the history of this portion of Antarctica. This environmental impact assessment describes the proposed action, summarizes the scientific studies to be undertaken, and outlines remedial and protective measures, unavoidable adverse impacts, and alternatives to the proposed action. It is anticipated that the majority of the impacts will be abort-term and extremely localized, such as those associated with the camp and laboratory facility on the Ross Ice Shelf during the period of drilling. These impacts will be monitored throughout the RISP operations. The pristine nature of the surface should be restored fully within one year. It is stressed that the likelihood of penetrating a hydrocarbon trap is remote, but should this occur rendering an uncontrollable release of hydrocarbons, the impact on the environment could be quite severe. On a scale of 1 to 10 this possibility is assigned a value of 5.

Concentrations of alkali and alkaline earth elements in north Greenland glacial ice deposited during the past 100,000 years show marked variations over that time span. Prior to the Wisconsin Stage concentrations of Na, K, Mg and Ca sverage 36, 44, 6.3, and 18 microg/l respectively. Concentration levels rise gradually at the beginning of the Wisconsin Stage and peak at averages of 51, 29, 25, and 5.1 microg/l. Silicon concentrations increase by about a factor of 3 (over Sangamon levels of 100 microg/l) during the late Wisconsin Stage, indicating a significant influx of colian dust at that time. Although sulfate concentrations are high (280 microg/l) during the late third of the Wisconsin Stage, they remain relatively constant (100 microg/l) prior to and after that time; this might suggest that the Wisconsin Stage was not triggered by volcanism. Similar elemental concentrations measured in West Antarctic glacial ice deposited easential ly over the same time period as the Greenland material also increase during the late Wisconsin Stage, but to a much smaller extent than those in Greenland ice. CLE SIZE DISTRIBUTION.

The permeability and structure of four fine-grained soils were observed to be changed by freezing and thawing. In all cases freezing and thawing caused a reduction in void ratio and an increase in vertical permeability. The increase in permeability is attributed to the formation of polygonal shrinkage cracks and/or to the reduction of the volume of fines in the porces depending on material type. No definite relationships are established; however, it appears that the largest increase in permeability occurs for the soil of highest plasticity. of highest plasticity.

SEGREGATION FREEZING AS THE CAUSE OF SUCTION FORCE FOR ICE LENS FORMA-

Takagi, S., International Symposium on Ground Preezing, 1st, Bochum, Germany, March 8-10, 1978. Proceedings. Edited by H.L. Jessberger, Bochum, Ruhr University, 1978, p.45-51, 20 refs 32-3470

SOIL FREEZING, GROUND ICE, ICE LENSES, SOIL WATER MIGRATION, FROST HEAVE, PROZEN GROUND THERMODYNAMICS, SOIL STRUCTURE, SOIL PRESSURE, ANALYSIS (MATHEMATICS).

(MATHEMATICS).

A new freezing mechanism, called segregation freezing is proposed to explain the generation of the suction force that draws pore water up to the freezing surface of a growing ice lens. The segregation freezing temperature is derived by applying thermodynamics to a soil mechanics concept that distinguishes the mechanically effective pressure from the mechanically neutral pressure. The frost-heaving procedure is formulated as part of the solution of the differential equations of the simultaneous flow of heat and water, of which the segregation freezing temperature is one of the boundary conditions.

EFFECT OF FREEZE-THAW CYCLES ON RESILIENT PROPERTIES OF FINE-GRAINED

SOIL TEMPERATURE, MODELS.

Stress-deformation data for silt and clay subgrade soils were obtained from in-situ tests and laboratory tests, for use in mechanistic models for design of pavements that will experience freezing and thawing. Plate-bearing tests were run on in-service all-bituminous-concrete (ABC) pavements constructed directly on silt subgrade, and on an experimental ABC pavement constructed on clay subgrade, applying repeated loads to the pavement surfaces while the subgrade was frozen, thawing, thawed, and fully recovered. Analysis of deflection data from the in-situ tests showed resilient modulis of the subgrade soils up to more than 10 GPa when frozen, as low as 2 MPa during the thawing period, and up to more than 100 MPa when fully recovered. Analysis of the laboratory tests, which gave moduli comparable to the latter values, showed that resilient modulus and Poisson's ratio in the thawed and recovering conditions can be expressed as a function of the stress rate, the moisture content, and the dry density.

KOTZEBUE HOSPITAL—A CASE STUDY.

Crory, F.E., Conference on Applied Techniques for Environments, Anchorage, Alaska, May 17-19, B. Proceedings, Vol.1, New York, American So-of Civil Engineers, 1978, p.342-359, 10 refs.

BUILDINGS, SETTLEMENT (STRUCTURAL), PERMAFROST BENEATH STRUCTURES, FOUNDATIONS, SOIL TEMPERATURE.

FOUNDATIONS, SOIL TEMPERATURE.
Construction of the hospital was started in late 1959 and completed in September 1961. The hospital is a single-story structure, supported on insulated perimeter wall footings, with intermediate footings for the support of roof columns and grade beams. All floors are slab-on-grade concrete. Wall cracking was in evidence in the first year of occupancy. A void of more than a foot was found between the floor slab and the gravel fill in August, 1963. At the request of the U.S. Public Health Service, USA CREEL conducted soil explorations and installed ground temperature assemblies and vertical movement points within the building and around the perimeter of the foundation distress. The performance of the hospital through 1976 clearly indicates the settlement associated with the thawing of the underlying permafrost with time. Soil and permafrost conditions in the village of Kotzebue are described in light of the conditions disclosed in the hospital ares.

EFFECTS OF MOISTURE AND FREEZE-THAW
ON RIGID THERMAL INSULATIONS: A
LABORATORY INVESTIGATION.

Kaplar, C.W., Conference on Applied Techniques for Cold Environments, Anchorage, Alaska, May 17-19, 1978. Proceedings, Vol.1, New York, American Society of Civil Engineers, 1978, p.403-417, 13 refs. 32, 1628

THERMAL INSULATION, ABSOMOISTURE, FREEZE THAW TESTS. ABSORPTIVITY.

MOISTURE, FREEZE THAW TESTS.

Laboratory observations on the effects of moisture absorption and freeze-thaw on various thermal insulation boards commonly used in construction beneath slabs on grade, in roofs, and in perimeter insulation of foundations were made under the too distinctions. Test specimens were submerged in water and buried in moist soil for periods ranging up to 36 months. Selected soaked specimens submerged in water were subjected to 15 and 30 freeze-thaw cycles. The study showed that:

1) None of the materials was completely resistant to moisture absorption under all test conditions; 2) A number of extruded polystyrene boards were more absorbent than the extruded polystyrene boards were more absorbent than the extruded types; and 4) Alternate freezing and thawing of rigid insulation in presence of free water was either destructive or increased moisture absorption in most of the tested materials; and 5) Cellular glass, normally highly moisture resistant in soaking moisture assorption in most of the tested materials; and 5) Cellular glass, normally highly moisture resistant in soaking tests, suffered extremely severe deterioration in freeze-thaw tests. This study clearly demonstrated that only highly moisture-resistant rigid thermal insulations should be used under conditions subject to free water and alternate freezing

DESIGN CONSIDERATIONS FOR AIRFIELDS IN NPRA.

Crory, F.E., et al, Conference on Applied Techniques for Cold Environments, Anchorage, Alaska, May 17-19, 1978. Proceedings, Vol.1, New York, American Society of Civil Engineers, 1978, p.441-458, 6 refs. Berg, R.L., Burns, C.D., Kachadoorian, R. 32-3631

AIRCRAFT LANDING AREAS, FROZEN SAND, FROZEN GRAVEL, PETROLEUM INDUSTRY.

FROZEN GRAVEL, PETROLEUM INDUSTRY.
Two exploratory wells, at Inidgok and Tunalik, will be spudded in the spring of 1978. The well sites require airfields for Hercules aircraft during the entire drilling operation. Design and construction problems for the two airfields are compounded by the constraint that they be built in winter and in accordance with environmental requirements which necessitate that all fill and gravel be transported over snow roads. Laboratory studies conducted at USACREL showed that fills of frozen sitly sand, the only locally available borrow at Inigok, have a greater potential for settlement upon thawing than the in-situ sands in cut sections. Several design options were considered for the airfields, drill pads and short connecting roads which must be usable all year. These included (1) gravel over sand, (2) gravel over insulation on sand, (3) landing mat with insulation, and (4) landing mat without insulation. Some of these concepts were evaluated at USAEWES, using large-scale test sections. In conjunction with the airfields, additional test sections are planned to evaluate different design concepts for runways, drill pads and roads to be built for the 1979 drilling program. This paper describes studies associated with the lnigok airfield.

EFFECTS OF SUBGRADE PREPARATION UPON FULL DEPTH PAVEMENT PERFORMANCE IN COLD REGIONS.

Zaton, R.A., Conference on Applied Techniques for Cold Environments, Anchorage, Alaska, May 17-19, 1978. Proceedings, Vol.1, New York, American Society of Civil Engineers, 1978, p.459-473, 8 refs. 32-3632

BITUMINOUS CONCRETES, COLD WEATHER PERFORMANCE, SUBGRADE PREPARATION, FROST HEAVE.

FROST HEAVE.

In September, 1973, a "full-depth" road test section was constructed at the U.S. Army Cold Regions Research and Engineering Laboratory (CRREL), Hanover, New Hampshire. Due to weather and time constraints, the subgrade beneath the asphalt concrete pavement was not properly prepared (blended, mixed, and made as uniform as possible). The road is in a cut area on an 8% alope and intersects horizontal layers of varved silts, silty sands, and sandy materials which are highly frost susceptible. The first winter, surface differential heaves of up to 5 inches in 5 feet occurred. The following summer, the subgrade was removed for 100 feet to a depth of 24 inches and 100 feet to a depth of 12 inches. The material was mixed, blended, and dried before placing back into the roadway in 6-inch compacted lifts. The succeeding two winters' performance has shown very marked improvement with relatively uniform heaving of the pavement surface. This shows, in conjunction with other CRREL highway pavement test sections, the importance of proper subgrade preparation for pavements in cold regions over frost-susceptible soils.

STORM DRAINAGE DESIGN CONSIDERA-TIONS IN COLD REGIONS.

Lobacz, E.F., et al, Conference on Applied Techniques for Cold Environments, Anchorage, Alaska, May 17-19, 1978. Proceedings, Vol.1, New York, American Society of Civil Engineers, 1978, p.474-489, 12 refs.

DRAINAGE, AIRCRAFT LANDING AREAS, ICE CONTROL, COLD WEATHER OPERATION.

CONTROL, COLD WEATHER OPERATION.

This paper, based on the authors' recently revised design manual for drainage facilities at Army and Air Force airfields and heliports, adapts previously used U.S. hydraulic design criteria to the special conditions prevailing in arctic and subarctic regions. Design runoff supply rates for surface drainage are derived from rainfall plus snowmelt minus infiltration, three factors for which typical values are given, for both permafrost and unfrozen ground situations. Guidelines are discussed for other drainage design requirements such as structural, durability, maintenance, and, of major significance in cold regions, environmental impact considerations and debris and icing control. Because of the importance of control and prevention of icings in and near drainage structures, applicable principles formulated by CRREL and other researchers are enunciated. While primarily intended for design of storm drain pipes, appurtenances and open drainage ditches serving airfields and heliports, the principles outlined are also generally suitable for culverts and drainage for facilities such as roadways, parking lots, and built-up areas in the Arctic and Subarctic.

TECHNIQUES FOR USING MESL (MEMBRANE ENCAPSULATED SOIL LAYERS) IN ROADS AND AIRFIELDS IN COLD REGIONS Smith, N., Conference on Applied Techniques for Cold Environments, Anchorage, Alaska, May 17-19, 1978. Proceedings, Vol. 1, New York, American Society of Civil Engineers, 1978, p.560-570, 19 refs. 32-3640

SOIL TEXTURE, SOIL WATER, SOIL COMPACTION, WATERPROOFING, LAYERS.

TION, WATERPROOFING, LAYERS.

Membrane encapsulation of fine-grained soils to prevent soil moisture intrusion can provide an option to the use of more expensive select granular soils as structural layers in roads and airfields, even in cold regions. Silts and clays compacted at, or slightly below, optimum moisture contents can provide high bearing strengths and are not subject to moisture migration or detrimental frost heaving during closed system (membrane encapsulated) freezing. Central Alaska has an abundant supply of silts, and the semi-arid climate is ideal for air-drying those that have an in-situ moisture content above optimum. In other areas it might not be economically or technically feasible to dry the soils to the required moisture content for encapsulation unless granular soils are extremely scarce.

ICE COMPOSITION, CHEMICAL ANALYSIS, ICE CORES, GREENLAND.

ICE CORES, GREENLAND.
Chemical analysis for Na, Cl, Al, Mn and V of surface snows and deeper ice core samples from station Milcent, Greenland, indicates a terrestrial or marine origin for these constituents. Pre-1900 enrichment factors, based on average crustal composition, are high for Zn and Hg and appear to be related to the volatility of these elements. A comparison of pre-1900 and 1971-1973 concentrations of V and Hg shows no decided increase due to industrial production, yet the relative abundance of Zn increased from 12 to 32 over this time period. The chemical composition of ancient ice is extremely useful in interpreting modern aerosols.

TRACER MOVEMENT THROUGH SNOW.

Colbeck, S.C., International Association of Hydrological Sciences. Publication, 1977, No. 118, International Symposium on Isotopes and Impurities in Snow and Ice, Grenoble, Aug. 28-30, 1975, p.255-262, In English with French summary. 19 refs. 32-3840

SNOW COMPOSITION, MOISTURE TRANSFER. IMPURITIES.

Impurities flowing with water through snow undergo hydrody-namic dispersion. Solutions describing the distribution of impurities are hard to obtain for realistic boundary conditions. The movement of impurities in snow is approximated here by neglecting second-order effects on their movement.

TUNDRA SOILS, THERMAL CONDUCTIVITY, TUNDRA VEGETATION, SOIL TEMPERA-TURE, TEMPERATURE MEASUREMENT.

TURE, TEMPERATURE MEASUREMENT.

Measurements of temperature and of thermal conductivity for two summer periods were carried out on wet organic surface materials and underlying mineral soils at Barrow, Alaska. Precise temperatures were measured by means of calibrated thermistors placed at accurately known depths, from which temperature gradients to a depth of 1.0 m are calculated. Thermal conductivities were measured by the transient-heating probe method, both in-situ and in the laboratory. The observed conductivity of the organic layer was between that of moist sir (0.1 W/mK) and that of water (0.6 W/mK); the conductivity of the silt soil depended on the state of freezing. The measured data are combined to calculate summer heat fluxes to a depth of 1.0 m, from which the thermal transition of the active layer from initial thawing to incipient freezing is described and analyzed.

Pulsed nuclear mag. etic resonance (NMR) techniques have been developed and utilized to determine complete phase composition curves for three soils. This promising new technique offers a non-destructive method for measurements of unfrozen water contents in frozen soils from -0.2C through -23C. The results show that unfrozen water contents determined by this technique depend upon ice content (i.e. total water content). These results are content to the soil of total water content). These results are contrary to earlier assumptions based on results which indicated that unfrozen water contents are a function of temperature only. These findings show great promise in the discrimination of unfrozen water associated with mineral grain boundaries and the ice-water interfaces of the poly-crystalline ices present in soil-

GEOECOLOGICAL MAPPING SCHEME FOR ALASKAN COASTAL TUNDRA.

Everett, K.R., et al, International Conference on Permafrost, R.R., et al, international Conference on Fer-mafrost, 3rd, Edmonton, Alberta, Canada, July 10-13, 1978. Proceedings. Vol.1, Ottawa, National Re-search Council of Canada, 1978, p.359-365, With Rus-sian and French summaries. 8 refs.

TUNDRA, MAPPING, CHARTS, VEGETATION PATTERNS, TUNDRA SOILS, UNITED STATES

ALASKA.

A unified geoecological mapping system has been developed for northern Alaska which recognizes in a given area a suite of landforms whose geomorphic elements control the composition and distribution of vegetation and soil. Within each landform boundary a fractional code is displayed in which the numerator consists of the geomorphic feature and its characteristic vegetation stand presented as a series of alpha-numeric units. The denominator is comprised of three elements: the soil(s), the landform type and its mean slope. Bach map contains an annotated list of code symbols and is accompanied by a text in which the characteristics of the code components are discussed. The advantages

of such a mapping technique include: (1) integrating on a single base a large body of diverse data into a relatively few easily detected environment units; (2) the derivation of any number of special purpose maps by selecting components of the code and/or related analytical data; (3) permitting an expansion of the code to include other kinds of geotechnical us environmental data.

Radiowave surface impedance (SI) and LF (200-400 kHz) and VLF (10-30 kHz) and magnetic induction (MI) methods were used to investigate permafrost properties and distribution in the Pairbanks and Copper River Basin areas of Alaska. Recently developed portable field instruments were used. The sites contained a range of materials and ground ice of varying volume and type. Galvanic resistivity soundings and existing borehole data provided ground truth for data comparison. Local plane wave interpretations of the LF and VLF apparent resistivity and phase data correlated with subaurface conditions. Frequencies in the LF band were most sensitive to permafrost conditions at the sites studied while VLF frequencies were more affected by conductive materials underlying the permafrost. The MI technique surface impedance (SI) and LP (200-400 kHz)

also correlated with subsurface control, but the coil spacing used limited the instrument's depth of penetration, making it more sensitive to variations in the active layer than the

SUBSEA PERMAFROST, DRILLING, DRILL CORE ANALYSIS, FROZEN ROCK TEMPERA-TURE, BEAUFORT SEA.

TURE, BEAUFORT SEA.

Core samples, cone penetration resistance and temperature data obtained from subsea sediments near Prudhoe Bay, Alaska, provided the basis for this study. The sites were located 1 to 17 km from shore in 2 to 12 m of water Maximum hole depth was 50 m. The materials at the drill sites included sands and gravels overlain by 4.5 to 7.5 m of silts and clays. No ice-bonded materials were observed, although thermal data indicated that permafrost was present. Index property, traixial compressive strength, consolidation and permeability data were obtained in the laboratory. Strengths ranged between 25 and 270 kPa for the fine material. Highly overconsolidated clays were encountered at the site farthest from shore. The preconsolidation pressure was estimated to be 1.5 MPa. Based on considerations of geologic and climatic history, it is proposed that the overconsolidation is a result of freezing and thawing

MP 1105 STRENGTH AND DEFORMATION OF FROZEN

Haynes, F.D., International Conference on Perma-frost, 3rd, Edmonton, Alberta, Canada, July 10-13, 1978. Proceedings. Vol.1, Ottawa, National Re-search Council of Canada, 1978, p.655-661, With Rus-sian and French summaries. 20 refs. 32-3760

FROZEN FINES, TENSILE STRENGTH, COM-PRESSIVE STRENGTH, FROZEN GROUND TEMPERATURE DEFORMATION.

TEMPERATURE, DEFORMATION.
Results are given for tests made in uniaxial tension and uniaxial compression on frozen Fairbanks silt. These constant displacement rate tests were made over a strain rate range from .00016/s to 2.9/s and a temperature range from OC to -57C. Over these ranges athe compressive strength increased about one order of magnitude, while the tensile strength doubled over the strain rate range and increased about one order of magnitude over the temperature range. For increasing strain rate and decreasing temperature, the specific energy for the compression tests and the modulus increased; but the specific energy for the tension test decreased; but the specific energy for the tension tests and temperature. The increase in strength with higher strain rates and lower temperatures is explained by the strength of the ice matrix, changes in the unfrozen water content, and intergranular friction.

Stress-deformation data for silt subgrade soil were obtained from in-situ tests and laboratory tests, for use in mechanistic models for design of pavements affected by frost action. Plate-bearing tests were run on bituminous concrete pavements constructed directly on a silt subgrade, applying repeated loads to the pavement surface while the silt was frozen, thawing, thawed, and fully recovered. Repeated-load laboratory triaxial tests were performed on the silt in the same conditions. Analysis of deflection data from the in-situ tests showed resiliant moduli of the silt as low as 2000 kPa for the critical thawing period, and 100,000 kPa or higher when fully recovered. Analysis of the laboratory tests, which gave moduli comparable to the latter values, showed that resilient modulus during recovery from the thawweakened condition can be modeled as a function of the changing moisture content. changing moisture content.

TUNNELS, PERMAFROST CONTROL, COOL-ING SYSTEMS.

ING SYSTEMS.

Tunnels and shafts in permafrost encounter special portal problems because of instability of surface materials during thaw, tendency for ice formation within the tunnel from annual thaw zone seepage, and necessity for coutrol of six temperatures within the tunnel during summer. In constructing a tunnel in permafrost at Fox, Alsaka, these problems were successfully solved. The unstable ground slope at the tunnel entrance was stabilized by use of a blanket of clean natural gravel. Refrigerant pipes imbedded in the backfill above the portals were used with a mechanical refrigeration system to insure a frozen zone around the tunnel where seepage would otherwise enter in summer. An insulated bulkhead containing doors permitted exclusion of warm summer sir. Batrance to a vertical shaft connecting to the rear of the tunnel was kept shaded in order to minimize seepage entrance in summer.

Facilities at Longyearbyen were designed and are being operated with an appreciation for the importance of press ving permafrost. Portions of the network of gravel roads and paved runway were constructed on ice-rich permafrost. Ditpermafrost. Portions of the network of gravel roads and paved runway were constructed on ico-rich permafrost. Ditches, culverts and bridges have been sized to accommodate large peak flows since flash floods have occurred. Some difficulties have been experienced with progressive degradation of permafrost by surface and groundwater. Damming a low area and pumping out brackish water has created a year-round water supply lake. The post and pad foundation concept used extensively has proved quite successful. The hangar is an impressive use of an elevated floor above permafrost. Older buildings have been stabilized by adding alag insulation above supporting soils and installing open skirting below the first floor. Water lines and other utilities are supported on timber bents anchored in permafrost.

MP 1109 DETAILS BEHIND A TYPICAL ALASKAN PILE POUNDATION.

Tobiasson, W., et al, International Conference on Permafrost, 3rd, Edmonton, Alberta, Canada, July 10-13, 1978. Proceedings. Vol.1, Ottawa, National Research Council of Canada, 1978, p.891-897, With Russian and Prench summaries. 7 refs. Johnson, P. 32-3795

BUILDINGS, FOUNDATIONS, PERMAFROST BENEATH STRUCTURES.

BENEATH STRUCTURES.

When a warehouse at Barter laland burned down, a replacement was urgently needed. The new foundation consists of forty-five steel pipe piles, 25 m in diameter, set in 4.6 to 5.8 m deep holes made with a 4.6 m diameter auger. The annulus was backfilled with a sand-water sturry. Sturry freezeback was closely monitored using thermocouples. As freezeback was rapid, the contractor was allowed to set steel beams on a pile five days after it was installed and pour concrete ten days after the last pile was set. Groundwater problems during July required casing of augered holes with 5.1 m diameter pipe to a depth of 1 m. Mechanical difficulties and lack of a crane slowed pile installation, but contractor resourcefulness got the job done. Subsequent elevation surveys and thermocouple measurements indicate that the foundation is solidly frozen and stable.

LAND APPLICATION OF WASTEWATER IN PERMAPROST AREAS.

Sletten, R.S., International Conference on Permafrost, 3rd, Edmonton, Alberta, Canada, July 10-13, 1978. Proceedings. Vol.1, Ottawa, National Research Council of Canada, 1978, p.911-917, With Russian and French summaries. 14 refs.

WASTE WASTES TREATMENT, WATER TREATMENT, IRRIGATION.

TREATMENT, IRRIGATION.

Land application of wastewater can serve as a high performance treatment system, as a final disposal step for treated effluents, and as a pollabing step for partially treated effluents. Experimental stadies conducted near Fairbanks, Alaska, during 1974-76 investigated both high (5.5 to 152 meters/year) and low rate (0.6 to 5.5 m/yr) systems for the purpose of polishing sersted lagoon effluent to meet secondary treatment criteria. Results from the slow rate system indicate that drinking water quality can be achieved. However, even though nitrogen removal is not as great, the high rate (rapid infiltration) system is considered to be more feesible for cold climate conditions because the need for winter storage is less, the system does not rely on vegetainve uptake, and the free-draining, coarse-textured soils necessary for such systems can be found in alluvial valleys and coastal areas where many Arctic communities are located. For most westewater constituents, high rate systems are capable of sustained, effective performance in extreme climates.

RADAR ANISOTROPY OF SEA ICE DUE TO PREFERRED AZIMUTHAL ORIENTATION OF

Kovacs, A., et al, Arctic Ice Dynamics Joint Experiment. AIDJEX bulletin, Mar. 1978, No.38, p.171-201, 32 reft.
Morey, R.M. 32-3878
ICR CRESSION.

ICE CRYSTAL STRUCTURE, SEA ICE, OCEAN CURRENTS, RADAR ECHOES, ANISOTROPY.
Results of impulse radar, ice crystal c-axis and sub-ice current
measurements on the fast-ice near Narwhal Island, Alaska,
are presented. The crystal structure of the ice was found
to have a horizontal crystal c-axis with a preferred azimuthal
orientation. This orientation was found to align with the
direction of the current at the ice water interface. Impulse
radar reflection measurements revealed that the preferred
orientation of the sea ice crystal structure behaved as a
microvave polarizer. It was observed that when the antenna
B-field was oriented parallel with the c-axis of the crystal
platelets a strong reflection of the radar signal from the
bottom of the ice was obtained. However, when the
antenna B-field was oriented perpendicular to the c-axis,
no bottom reflection was detected. The results of this
study fully support earlier reports of sea ice in-homogeneity
and anisotropy in reference to both structure and electromagnetic energy transmission. CURRENTS, RADAR ECHOÉS, ANISOTROPY.

32-3942 REMOTE SENSING, DATA PROCESSING, SNOW WATER EQUIVALENT, SNOW DEPTH. SNOW WATER EQUIVALENT, SNOW DEPTH.

The prinary emphases of this analysis were to evaluate the accuracy of mapping the areal extent of snow and to determine the relationship between the water equivalent of the snowpack and the radiance obtained from the LANDSAT digital data. The test area selected for this task was the Dickey-Lincoln School Lakes Project located above the confluence of the St. John and Allagash Rivers in northern Maine. The computer algorithm utilized in this study uses two features—"color" and "alledo"— of the LANDSAT digital data to classify the multispectral data into land and water categories. Three snow courses (Allagash R. Beech Ridge and Ninemille By jekting snow depth and water equivalent data were located. This task was accomplished using computer-generated gray scale printouts (scale 1:24,000) and topographic maps. The preliminary results indicated that the snow radiance values remained approximately the same for a similar water equivalent value of 9.5 inches. Extrapolation of these radiance values for the entire watershed can be used to map the areal extent of snow cover/vegetation with a water equivalent value of 9.5 inches which enables computation of potential water runoff.

USE OF THE LANDSAT DATA COLLECTION SYSTEM AND IMAGERY IN RESERVOIR MANAGEMENT AND OPERATION. Cooper, S., et al, Waltham, Massachusetts, U.S. Army Corps of Engineers, 1977, c150p., Numerous refs. Buckelew, T.D., McKim, H.L., Merry, C.J. 32-3943 WATERSHEDS, REMOTE SENSING, SPACE-

WET SNOW, SNCW WATER CONTENT, POROSITY, SATURATION, MEASURING IN-STRUMENTS, ACCURACY, REMOTE SENSING. STRUMENTS, ACCURACY, REMOTE SENSING. Liquid saturation and porosity control most of the important material properties of wet snow, hence accurate measurements of these two parameters are of the utmost importance for both field research and glaciological applications. Nevertheless, most of the instruments in use are not capable of making accurate determinations of saturation. An error analysis shows that only direct measurements of the liquid volume can provide accurate values of water saturation, hence the melting calorimeter is inherently inaccurate. While centrifuges extract tome of the liquid for direct measurement, there is always some residual liquid left, depending on the grain size and structural parameters of the ice matrix. Therefore, some uncertainty exists over the interpretation of the data obtained from centrifuses. grain size and structural parameters of the ice matrix. Interfere, some uncertainty exists over the interpretation of the data obtained from centrifuges. High-frequency capacitance probes can be used either in situ or on the surface and are very sensitive to the volume of flquid present. Capacitance probes are by far the best of the available devices.

ICEBERGS, ICE COVER THICKNESS, RADAR BCHOES, ICE ISLANDS, CREVASSES, ICE CRACKS, ANTARCTICA—MCMURDO SOUND. CRACKS, ANTARCTICA—MCMURDO SOUND.
Results obtained with an impulse radar system used to profile the thickness of and detect cracks in a tabular icohergin McMurdo Sound, Antarctics, and an ice island in the Beautort See near Plaxman Island, Alsaka, are presented. Graphic records are shown of the radar impulse travel time which clearly reveal, for the first time, the bottom relief of each ice formation. Also detected in the antarctic icoherg was an echo signature from an infiltration-brine layer. The impulse radar signature of a 3-m wide crevasse in the McMurdo Ice Sheff is also shown. The time of flight of the radar impulse in the ice island is compared with a 24.03-m drill hole measurement of the ice thickness. The effective velocity of the radar impulse in the ice island was found to be 0.16m/ns and the effective delectric constant of the ice to be 3.5. The friedings show that tabular icebergs are flawed by cracks or crevasses which could be expected to propagate through the ice when an iceberg reaches the edge of the pack where it is subject to stresses induced by sea swell and waves. MATHEMATICAL MODELS, SOIL WATER MI-GRATION, HEAT TRANSFER, FROST HEAVE, FROST PENETRATION.

PROST PENETRATION.

A mathematical model of coupled heat and moisture flow in soils has been developed. The model includes algorithms for phase change of soil moisture and frost heave, and several types of boundary and initial conditions are permitted. The finite element method of weighted residuals (Galerkin procedure) was chosen to simulate the spatial regime and the Crank-Nicolson method was used for the time domain portion of the model. Comparison of simulated and experimental data illustrates the importance of unsaturated hydraulic conductivity. It is one parameter which is difficult to measure and for which only a few laboratory test results are available. Therefore, unsaturated hydraulic conductivities calculated in the computer model may be a significant source of error in calculations of frost beave.

SEA ICE, PRESSURE RIDGES, ICE MODELS.

SEA ICE, PRESSURE RIDGES, ICE MODELS.

The ice cover in the Beaufort Sea is characterized by extreme irregularities in thickness which are produced by the motion and resulting deformation of the sea ice. Pressure ridges, which are an integral part of this irregular and formidable ice cover, sea recognized as the largest and most hazardous ice formations. Here, a number of cross-sectional profiles of first and multi-year pressure ridges in the Beaufort Sea are presented, which include both free-floating and grounded ice forms.

The cross-sections of these multi-year ridges model with a constant sail to keel ratio and geometry. It is shown that the ice comprising multi-year ridges is

solid, with the interblock voids existing at the time of their formation being completely filled with ice. Several first-year pressure ridge profiles are also discussed, which indicate that these ridges cannot be represented by any one geometric model as their sail to keel ratios and geometries are quite variable.

ICE COVER EFFECT, ICE NAVIGATION, SEDI-MENT TRANSPORT.

MENT TRANSPORT.

This paper examines the hydrodynamics of vessel passage through a restricted channel and the resulting potential for sediment translocation.

Examples of field measurements are presented which show a complex pattern of changes in water current magnitude and direction. The constriction of the channel by a ship creates a drop in the water surface that travels with the ship. The application of the concepts of effective stress and upward seepage forces to the riverbed material predicts that the potential for sediment translocation increases upon the passage of this moving trough. Three modes of granular bottom sediment transport were observed bed load, saltation, and a process referred to as explosive liquefaction. liquefaction.

Calkins, D.J. 33-400

FRAZIL ICE, ICE FORMATION, TURBULENT FLOW, SUPERCOOLED WATER, ICE NUCLEI.

FLOW SUPERCOOLED WATER, ICE NUCLEI.

To study ice nucleation and heat transfer, frazil ice was produced experimentally under controlled conditions. Turbulence was generated by a moving grid in a turbulence jar, where water could be cooled below the freezing point. Frazil was observed by means of a schileren system and the number of ice particles was counted on photographs. No frazil ice formed, regardless of turbulence and foreign material, unless the water was seeded with ice nuclei. The number of particles grew during the experiment; the growth rate increased with greater supercooling and higher velocity of the grid. This indicates a multiplication process induced by secondary nucleation. The heat transfer per particle owns constant in all experiments within the accuracy of measurement. From these observations, it can be concluded that the total ice production is predictable if the heat transfer per particle can be estimated from turbulence data and if the number of particles can be calculated. A nucleation theory is, however, not available and is regarded as the crucial question.

ICE BOOMS, FLOATING STRUCTURES.

ICE BOOMS, FLOATING STRUCTURES.

The ability of an ice boom timber to restrain ice floes is governed by its capacity to float and to resist being overturned. Six mathematical equations that describe this capacity for a rectangular-shaped timber have been worked out and are presented here. The limits of each equation are also given. They are called righting moment equations, and from them dimensionless values of righting moment may be calculated. The equations have been evaluated for some general conditions, and for a few specific cases involving water and wood, and for one case concerned with designing a steel pontoon boom. The calculations were done by a computer program which is not included. The

data provided include three graphs and two tables of dimension-less values. All in all, the information should be very useful in evaluating new designs of ice boom timbers and

33-423

SEA ICE, DRIFT, WIND VELOCITY, CHANNELS
(WATERWAYS), ICE MODELS.

Models originally developed to describe the arching and
the movement of granular materials through hoppers or chutes
are spelled to arching and drift of pack ice in straits and
aults having lengths of 50 to 500 km. Verification of
the usefulness of the models is attempted by making comparisons with ice deformation patterns as observed via satellite
imagery in the Bering Strait region and in Amundsen Gulf.
The results are encouraging in that there is good correspondence between observed arching and lead patterns and those
predicted by theory. In addition, values determined via
the model for the angle of internal friction and the cohesive
strength per unit thickness are similar to values obtained
by other approaches. It is estimated that if the wind
velocity parallel to the Bering Strait exceeds 6 m/s, there
will be ice flow through the strait. A one-dimensional
formulation is presented, governing the ice pressure in a
straight channel when the ice is stationary due to an ice
arch or a boom.

RADAR ANISOTROPY OF SEA ICE DUE TO PREFERRED AZIMUTHAL ORIENTATION OF HORIZONTAL C AXES OF ICE CRYSTALS.

Kovacs, A., et al. Journal of geophysical research, Dec. 20, 1978, 83(C12), p.6037-6046, 36 refs. Morey, R.M. 33-2286

SEA ICE, RADAR ECHOES, ANISOTROPY, ICE CRYSTAL STRUCTURE, ELECTROMAGNETIC PROPERTIES, OCEAN CURRENTS.

PROPERTIES, OCEAN CURRENTS.

Results of impulse radar, ice crystal c axis, and subice current measurements on the fast ice near Narwhal Island, Alaska, are presented. The crystal structure of the ice was found to have a horizontal crystal c axis with a preferred azimuthal orientation. This orientation was found to align with the direction of the current at the ice-water interface. Impulse radar reflection measurements revealed that the preferred orientation of the sea ice crystal structure behaved as a microwave polarizer. It was observed that when the antenna B field was oriented parallel with the c axis of the crystal platelets, a strong reflection of the radar signal from the bottom of the ice was obtained. However, when the antenna B field was oriented perpendicular to the c axis, no bottom reflection was detected. The results of this study fully support earlier reports of sea ice inhomogeneity and anisotropy in reference to both structure and electromagnetic energy transmission.

EFFECT OF WASTE WATER REUSE IN COLD REGIONS ON LAND TREATMENT SYSTEMS. lakandar, I.K., Journal of environmental quality, July-Sep. 1978, 7(3), p.361-368, 26 refs.

WATER TREATMENT, WASTE DISPOSAL, COLD WEATHER TESTS, SOIL CHEMISTRY.

COLD WEATHER TESTS, SOIL CHEMISTRY.

The effect on ground water quality and soils and vegetation of treatment and disposal of municipal/industrial waste water on land in cold regions was investigated using air outdoor test cells. Winter application of waste water was feasible even at very cold air temperatures (<0.0°C) at the New Hampshire test site. High NO3-N concentrations were observed in all treatments (5-15cm/week) in both soils in early summer. This was explained as leaching of NH4-H stored over the winter months after its oxidation to NO3 in early spring. The principal mechanism for nitrogen removal was found to be plant uptake, which was seasonally dependent. Application of 15 cm of secondary effluent per week to a sandy loam soil was not feasible because of the presence of >10mg/liter NO3-N in the leachate for >9 mo/year. Application of salts for road decicing during winter resulted in relatively higher concentrations of salts and Cl in the ground for a short period of time.

MENT.

MEN'I.

The objectives of this Symposium are to summarize the state of knowledge of the practical aspects of the treatment of wastewater by land application and to identify the suitable approaches for the design of such land treatment systems. The topics included are: site selection considerations, case studies of national and international concern, health effects of land treatment systems, pretreatment considerations, uses of wastewaters in agricultural and forest systems, monitoring, modeling and design criteria. The Proceedings are published or wastewaters in agricultural and forest systems, monitoring, modeling and design criteria. The Proceedings are published in two volumes. Volume 1 contains the invited papers presented and discussed at the conference. Volume 2 contains shorter papers about on-going research that were selected from the responses received following a call for abstracts.

EVALUATION OF THE MOVING BOUNDARY THEORY IN CARCY'S FLOW THROUGH POR-

Nakano, Y. International Symposium on the State of Knowledge in Land Treatment of Wastewater, Aug. 20-25, 1978, Hanover, New Hampahire. Proceed-ings, Vol.1, Hanover, U.S. Army Cold Regions Re-search and Engineering Laboratory, 1978, p.142-151, 22 refs

BOUNDARY VALUE PROBLEMS, SOIL WATER MIGRATION, POROUS MATERIALS, ANALYSIS (MATHEMATICS), THEORIES.

YSIS (MATHEMATICS), THEORIES.

Traditionally in hydrology and soil physics, neither the water table nor the wetting front in Darcy's flow were believed to be singular surfaces. Recently, a new and conflicting theory has been advanced, using two different approaches. It has been shown, based upon continuum physics, that across both the water table and the wetting front local acceleration generally suffers a non-zero jump, and these two boundaries can be interpreted as acceleration waves. This interpretation was found consistent with reported regularity results obtained from a purely mathematical viewpoint.

EVALUATION OF N MODELS FOR PREDICTION OF NO3-N IN PERCOLATE WATER IN LAND TREATMENT.

Iskandar, I.K., et al, International Symposium on the State of Knowledge in Land Treatment of Wastewater, Aug. 20-25, 1978, Hanover, New Hampshire. Proceedings, Vol.1, Hanover, U.S. Army Cold Regions Research and Engineering Laboratory, 1978, p.163-169, 51 refs Selim. H.M.

WATER TREATMENT, SOIL CHEMISTRY, SEEPAGE, MATHEMATICAL MODELS.

SEEPAGE, MATHEMATICAL MODELS.

Nitrogen simulation models developed to describe one or more processes in agricultural soils can be adopted for land treatment. The most important processes in the simulation of N transformations for prediction of N in percolate water in land treatment are: intrification, dentirification, plant upstake and exchange of NH4 with the soil. The N model must be incorporated into a moisture flow model. It was concluded that the Michaelis-Menten type model is the most appropriate, although the first order kinetic may be used to describe nitrification process. Modeling the denirification process in slow infiltration must include biodegradable carbon and dissolved oxygen as limiting factors. Although several large models are available to simulate and predict N in leachate in land treatment, a need for a simplified model that can be tested in the field is apparent.

MP 1149 MP 1147 NITROGEN BEHAVIOR IN LAND TREAT-MENT OF WASTEWATER: A SIMPLIFIED MENT OF MODEL.

Iskandar, I.K. 33-654

WASTE TREATMENT, WATER TREATMENT, SOIL CHEMISTRY, SEEPAGE, MATHEMATICAL MODELS.

CAL MODELS.

A simplified mathematical model was developed to describe transformations and transport of nitrogen under transient soil water flow conditions. Kinetic reactions were assumed to govern the nitrification and denirrification processes. A macroscopic approach was used to incorporate plant uptake of water as well as NO3-N and NH4-N from the soil acolution. The sensitivity of the model to changes in rate of N transformation, N crotake by plants, and schedule and amounts of N application were also investigated. The model can be used as a tool to predict the fais of nitrogen in land treatment systems. The model is flexible and can be adapted to incorporate various nitrogen transformation mechanisms as well as layerings in the soil profile.

MP 1150 OVERVIEW OF EXISTING LAND TREATMENT SYSTEMS

Iskandar, I.K., International Symposium on the State of Knowledge in Land Treatment of Wastewater, Aug. 20-25, 1978, Hanover, New Hampshire. Proceedings, Vol.1, Hanover, U.S. Army Cold Regions Research and Engineering Laboratory, 1978, p.193-200, 34 refs.

WASTE TREATMENT, WATER TREATMENT, SOIL CHEMISTRY, HISTORY.

This paper reviews existing systems of land application of wastewater. Particular emphasis is placed upon the historical philosophy of the utilization of the natural soil-plant system for purifying wastewater, reasons for the success or failure of the older systems, and experience gained from their design, construction and operation.

UPTAKE OF NUTRIENTS BY PLANTS IRRI-GATED WITH MUNICIPAL WASTEWATER EF-

Clapp, C.E., et al, International Symposium on the State of Knowledge in Land Treatment of Wastewater, Aug. 20-25, 1978, Hanover, New Hampshire. Proceedings, Vol.1, Hanover, U.S. Army Cold Regions Research and Engineering Laboratory, 1978, p.395-404, 21 refs

NUTRIENT CYCLE, IRRIGATION, WASTES, WATER TREATMENT, SOIL CHEMISTRY.

WATER TREATMENT, SOIL CHEMISTRY.

We present comparisons of plant nutrient uptake by corn and forage grasses when these crops were irrigated with secondary municipal wastewater effluent or treated with inorpanic fertilizer. Characteristic analyses of effluent from various locations are given for the macro plant nutrients as well as for quality indicators. The importance of the presence of varying amounts of N, P, and K in effluent studies is discussed. Micro elements in effluent are considered for their use to meet nutrient requirements of these crops as well as for their potential for environmental contamination.

33-001 SOIL WATER MIGRATION, SOIL CHEMISTRY, MATHEMATICAL MODELS.

MATHEMATICAL MODELS.

A numerical method is introduced to simulate the movement of conservative chemicals in soil by water. The method is essentially based upon a finite element aproximation to the equation of continuity, and each element constitutes a complete mixing cell. The number of cells represents a degree of mixing. The theoretical justification of the method is presented and the accuracy of the method is examined, using experimental data obtained from a large lyaimeter. It is found that the method can simulate the general trend of the movement of chemicals reasonably well, but fails to simulate the high frequency of variations that occur near the soil surface.

FREEZE THAW TESTS, ROADS, SUBGRADE PREPARATION, PROTECTIVE COATINGS, DY-NAMIC LOADS.

NAMIC LOADS.
Road test sections of impermeable membrane-enveloped silt and clay soils overlein with asphalt cement concrete were subjected to repetitive dynamic plate-bearing loadings to determine strength variations of the pavement systems during freeze-thaw cycles. The modulus values of the asphalt cement concrete vary inversely with its temperature by an order of magnitude in the temperature range of 110F to 30F. The resilient stiffness of the pavement system varied in the same manner by nearly a factor of eight. Despite the wide strength variations of the sections during freeze-thaw cycles, membrane enveloped fine-grained soils can be utilized instead of granular materials as base and subbase layers in flexible pavements in cold regions where moisture migration is a major concern. Without the membrane protection such fine-grained soils that experience frost heaving suffer severe bearing strength loss during thawing.

14(4), p.693-695, 5 refa. 33-641

RIVER ICE, ICE JAMS, MEASUREMENT, ICE COVER THICKNESS.

COVER THICKNESS.
River ice jam measurements have always been relatively difficult to obtain because of the uncertain stability of the floating ice mass. But recently two ice jams resolidified for about 3 weeks, allowing the ice thickness to be measured at several cross sections along their longitudinal profiles. The size distribution of surface ice floes in one of the jams was also evaluated from low-level serial photography. The ice jams were found to be thickest at the downstream end, of the order of 4-5 times the thickness of the ice cover before breakup, and decreased almost linearly in thickness upstream. The largest surface ice floes measured in one ice jam ranged from 0.27 to 0.05 of the river's average width (45m). The largest floes were at the downstream end, and floe size decreased progressively with distance upstream.

ICE MELTING, ARTIFICIAL MELTING, BUB-BLING, COMPUTERIZED SIMULATION.

BLING, COMPUTERIZED SIMULATION.
Results of laboratory experiments conducted to determine bubbler-induced heat transfer coefficients are reported. Implications and validity of results are discussed. As a second step, a procedure for computer-simulating the behavior of an ice aheet whose thickness is controlled by a bubbler system operating intermittently over a long period of time is developed. The simulation uses experimentally determined bubbler heat transfer coefficients, weather data, and characteristics, and desired performance as input data, and a finite difference method to solve the equations governing the ice thickness and temperature profile. Through an example simulation, the usefulness of the procedure in predicting ice thickness and temperature profile histories, and the effectiveness or suitability of a given bubbler system are demonstrated.

DECAY PATTERNS OF LAND-PAST SEA ICE IN CANADA AND ALASKA.

Bilello, M.A., Symposium on Sea Ice Processes and Models, Sep. 6-9, 1977. Proceedings, Vol.2, Seattle, University of Washington, 1977, p.1-10, 11 refs.

SEA ICE, FAST ICE, ICE COVER THICKNESS, DETERIORATION, METEOROLOGICAL FACTORS.

Weekly measurements of the thickness of land-fast sea ice made over a period of 10 to 15 years at a number of coestal locations in Canada and Alsaks were analyzed. That portion of the data relating to maximum ice thickness and decay (i.e., the decresse in ice thickness) are presented and examined. Many meteorological and marine factors affect the decay process. This study investigates the effects of two important weather elements; sir temperature and affect the decay process. This study investigates the effects of two important weather elements: air temperature and solar radiation. Complete and reliable air temperature data for each station made it possible to analyze the relationship between accumulated thawing degree-days (ATDD) and sea ice ablation. The relationship between ice decrease and

daily accumulated solar radiation was investigated; the results were comparable to those derived when ATDD was used as the dependent variable. Other factors affecting ice ablation and breakup, such as snow-ice formation, snow cover depth, and wind, are also discussed in the study.

NEARSHORE ICE MOTION NEAR PRUDHOE

SEA ICE, DRIFT, ICE TEMPERATURE, THER-MAL EXPANSION.

MAL EXPANSION.

Shorefast and nearshore pack ice motions in the vicinity of Frudhoe Bay, Alsaka, have been monitored for the spring seasons (March-June) of 1976 and 1977. From the base camp on Narwhal Island, a barrier island 25 km northeast of Frudhoe Bay, a ranging laser was used to measure distances to targets located on the fast ice within a 7 km radius of the island. To assess pack ice motions, a radar transponder system with tracking stations located on Narwhal and Cross Islands was used to monitor the positions of transponder system with tracking stations located on Narwhal and Cross Islands was used to monitor the positions of transponders placed on the pack ice as far as 37 km northeast of the islands. These results suggest that gyre movement or alippage of the nearshore pack ice in this area apparently does not begin until early to mid-summer. The pack ice in this area responds slowly, and only weakly to local winds. The mesoscale displacements that occurred took place only after several days of consistent offshore winds. This indicates that a significant shoreward stress originating in the more distant pack heavily influences the dynamics of this nearshore area.

MP 1163 CHARACTERIZATION OF THE SURFACE ROUGHNESS AND FLOE GEOMETRY OF THE SEA ICE OVER THE CONTINENTAL SHELVES OF THE BEAUFORT AND CHUKCHI SEAS.

SEA ICE DISTRIBUTION, SURFACE ROUGHNESS, SIDE LOOKING RADAR, PRESSURE

RIDGES.

This paper reports on observations primarily made during the late winter and early spring of 1976 when the ice cover was at its maximum extent, and very few leads were observed.

The primary sensors used were a laser profilomenter and an X-band side-looking airborne radar (SLAR) system. The heaviest ridging was found at Barter Island and there was a general decrease in the number of ridges as one moved west into the Chukchi Sea. There was no strong variation in the mean ridge height along the coast. moved west into the Chukchi Sea. There was no strong variation in the mean ridge height along the coast. There was no systematic areal variation in mean ridge height normal to the coast. There was also no correlation between mean ridge height and the number of ridges per km as has been reported by previous investigators. An analysis was also made of the probability of encountering very large ridges. SLAR imagery gives the size distribution of multiyear ice flocs within the nearthore ice pack, and the variation in the areal percentage of deformed ice as a function of distance from the coast. This latter parameter showed a steady the coast. This latter parameter show

MODELING PACK ICE AS A VISCOUS-PLAS TIC CONTINUUM: SOME PRELIMINARY RE-SULTS.

Hibler, W.D., III, Symposium on Sea Ice Processes and Models, Sep. 6-9, 1977. Proceedings, Vol.2, Seattle, University of Washington, 1977, p.46-55, 21 refa

PACK ICE, VISCOUS FLOW, PLASTIC FLOW, ICE DEFORMATION, ICE MODELS, MATHEMATICAL MODELS.

EMATICAL MODBLS.

A dynamic thermodynamic model of pack ice is presented, which treats the ice as a nonlinear viscous continuum characterized by both bulk and shear viscosities and a pressure term with the viscosities being functions of the deformation rate and the pressure. The pressure is parameterized as a function of the compactness and mean thickness of the ice. This formulation allows the viscous continuum approach to be retained while allowing the system to deform in a plastic manner. The model is formulated in a fixed Eulerian raid and the dynamical equations are compiled to confining plastic manner. The model is formulated in a fixed Eulerian grid, and the dynamical equations are coupled to continuity equations for compactness and mean ice thickness which include thermodynamic source and sink terms. In the numerical scheme the dynamical equations of motion, in finite difference form, are integrated implicitly and the ice thickness equations are integrated explicitly. The model is applied to the Arctic Basin and integrated at one-day steps for up to eight years in order to obtain steady state results for both ice thickness and drift. Two cases are

MP 1165 FINITE ELEMENT FORMULATION OF A SEA ICE DRIFT MODEL.

Sodhi, D.S., et al, Symposium on Sea Ice Processes and Models, Sep. 6-9, 1977. Proceedings, Vol.2, Seattle, University of Washington, 1977, p.67-76, 10 refs. Hibler, W.D., III.

SEA ICE, DRIFT, MATHEMATICAL MODELS.

The complete boundary value problem of a linear viscous sea ice drift model is presented, using the finite element method; and the formulation includes the inertial force term method; and the formulation includes the imertial force term in the governing equation of motion. The results of the computations of the steady-state ice velocities in the Arctic Cocens are presented, using mean seasonal geostrophic wind data and available current information. The effect of varying boundary conditions and the viscosity parameters is examined. On a much smaller scale, this model has been applied to the study of non-steady drift of pack ice through the Strait of Belle lale (between Newfoundland and Labrador) where strong tids streams and ocean currents move the pack ice back and forth. Using idealized sinusoidal variations of the tidal streams at its found that the time lag between the water and the ice velocities is related to the viscosity parameters, which indicates that the ice is not drifting freely; and the boundaries affect the time constant of the simplified first order model of the ice drift through the Strait.

33-1573

ELECTRICAL RESISTIVITY, ABRIAL SURVEYS, VERY LOW FREQUENCIES, TOPOGRAPHIC EFFECTS, ELECTRIC FIELDS.

Arborne wavetilt resistivity surveys and profiles at VLP have been analyzed for the effects of topography, altitude, and wavetilt plases and amplitude. Topographic relief is known to affect at least one electric field component, flight altitude often varies over relief, and phase depends on the earth's resistivity stratification and the relative strength of the least the confidence of the control of the cont earth's resistivity stratification and the relative strength of displacement to conduction current. A mountainous area in northern Maine of predominantly slate, but containing an igneous stock, was surveyed at 150 m mean flight attitude. The 150-m survey was repeated at 300 m and two of the 150-m slight lines were repeated at a total of three other attitudes. A comparison of the 150-m survey with the topography and with the 300-m survey revealed that although most of the resistivity information of the 150-m survey was retained at 300 m, serious differences arose due to topographic influences. Profiles of the individual electric field components at the various altitudes then revealed that topography was topographic influences. Frofiles of the individual electric field components at the various altitudes then revealed that topography was distorting resistivity values through its effect upon only the vertical component of the electric field. The separate influences of phase and amplitude were analyzed using the results of a ground survey of the total, complex surface impedance. The phase of the tilt proved to be important in the airborne differentiation of the rock types.

REMOTE SENSING, CONSTRUCTION MATERIALS, GEOLOGIC STRUCTURES.

MATERIALS, GEOLOGIC STRUCTURES.

Pourteen surficial geology units were delineated in a 2850 at km area in northern Maine. These units included: alluvial fan, alluvial terrace, esker, floodplain, glacial moraine, kame, kame terrace, outwash, outwash terrace, bedrock, till, ill over bedrock, were outwash and wet till. The surficial geology units were field checked and then updated from the field reconsissance. The depths of the surficial geology units were estimated utilizing borehole data, field measurements and seismometer data. The areal extent of each surficial geology unit was quantified, using a planimetric color densitometer. The volumes of construction material were computed based upon these areal determinations and estimated depths. The volume estimates, compared with the estimates of required construction material, showed that more material could be found within the prescribed area around the dam and dike sites than was required for construction. It is believed that the east- and northeest-trending lineaments in this area are thrust faults dipping 45 deg to the northessts. The north-trending and N60W lineaments are probably strike-slip normal and reverse faults dipping 80 deg to nearly vertical. Future movement along these faults should be negligible.

MP 1148 CREEP RUPTURE AT DEPTH IN A COLD ICE

ICE SHEETS, ICE CREEP, FRACTURING, SEIS-MIC SURVEYS.

MIC SURVEYS.

Experimental evidence has not supported the hypothesis that tectonic processes operating within glaciers and ice sheets are analogous to those in the Earth. However, evidence of the existence of discrete shear planes within the antarctic ice sheet (31-1071 or F-17742) and evidence described here relating to the Greenland ice sheet indicate that faulting takes place at depth in cold ice sheets. The evidence suggests reconsideration of the concept of correspondence between flow and rupture at depth in the Earth and in cold ice sheets, as suggested earlier. Direct investigations at depth in ice sheets are made with relative ease as compared to the nearly impossible task of direct measurements in the Earth's mantle.

MP 1169 EFFECT OF INUNDATION ON VEGETATION AT SELECTED NEW ENGLAND FLOOD CON-TROL RESERVOIRS.

McKim, H.L., et al, Symposium on Remote Sensing for Vegetation Damage Assessment, February 1978. Proceedings, 1978, 13p., 13 refs. Gatto, L.W., Merry, C.J., Cooper, S.

REMOTE SENSING, INFRARED PHOTOGRA-PHY, VEGETATION PATTERNS, DAMAGE, PHY, VEGE FLOODING.

PLOODING.

The effect of inundation on vegetation caused by the regulation and impoundment of water at six New England flood control reservoirs during a June-July 1973 flood was assessed from color infrared photography and corroborative ground surveys. Percent of damaged trees was assessed on a pattern recognition and coloration basis. Correlative ground truth data showed that the deciduous trees, particularly silver maple and red oak, were least affected and that coniferous trees, especially white pine, were most affected by siltation and inundation. Much of the understory vegetation, i.e., American and Eastern hop hornbeam, lost all leaves after inundation, but new buds and shoots appeared by late September 1973. A critical relationship, determined from ground transect profiles tho "ing the relationship between species usceptibility and inundation time, was that trees completely covered by flood waters for more than 90 hours showed the most apparent damage.

damage.

27 refs. See also 32-3470 and 32-4368.

ICE LENSES, ICE FORMATION, SOIL WATER, SOIL FREEZING, HEAT TRANSFER, FROST HEAVE, ANALYSIS (MATHEMATICS).

HEAVE, ANALYSIS (MATHEMATICS). A new concept of the freezing of water, called aggregation freezing, is proposed to explain the creation of the suction force that draws pore water up to the interface of a growing ice lens. The temperature of segregation freezing is shown to be lower than that of normal freezing (in situ freezing). This difference determines the pressure that the ice lens sexerts while growing and carrying the overlying weight. On the assumption that the soil structure is rigid, equations governing the simultaneous flow of heat and water are formulated and solved for the limit of time t to 0 with the combination of analytical and numerical methods. Numerical computation of the solution yields a result that is reasonable, compared with experience in laboratory and nature.

GLACIER FLOW, CREEP, ICE REFRIGERA-TION, MINING, DRILLING, ANALYSIS (MATH-EMATICS), ICE TEMPERATURE.

TION, MINING, DRILLING, ANALYSIS (MATH-EMATICS), ICE TEMPERATURE.

A scheme for cooling the lower portion of the edge of the Greenland ice sheet, which abuts a potential mining operation is examined. At the mine site, the ore body is overlain with ice. Once the overburden is removed, however, the adjacent ice is expected to flow toward the pit. One possible means of slowing this movement is to cool the ice below its present temperature to achieve a reduction in the creep rate and a retardistion of basal slip. The present study examines analytically the magnitude of cooling which may be accomplished by drilling a series of vertical holes about the periphery of the mine site. Refrigaration is accomplished by pumping a coolant downhole in a central pipe, then uphole in an annulus between the pipe and hole wall, and then through a thin walled pipe exposed to the cold surface climate above the ice sheet. Results of example calculations for various particular combinations of the free parameters are examined and include cooling requirements, hold spacing, pump requirements, and other parameters. Over a period of operation on the order of a year of more, it appears possible to cool a substantial part of the lower area of the glacier on the order of 1 to -2C, using a hole spacing that is considered reasonable. The results of the study are to be used as input to a detailed glacier flow study.

REMOTE DETECTION OF MASSIVE ICE IN PERMAPROST ALONG THE ALYESKA PIPE-INE AND THE PUMP STATION FEEDER GAS PIPELINE.

Kovacs, A., et al, ASCE Pipeline Division Specialty Conference, New Orleans, Louisians, Jan. 13-17, 1979. Proceedings. Pipelines in adverse environ-ments; a state of the art, Vol.1, New York, N.Y., American Society of Civil Engineers, 1979, p.268-279,

LINES.
Field soundings using an impulse radar system were carried out during May 1976 along a section of the Alyeska Pipeline near Pump Station 3 and the pump station feeder gas pipeline trench near the Happy Velley Camp, Alaska. The radar system, operating on the ground, provided a continuous profile of the near-surface geological structure of the permafrost. A unique dual antenna configuration produced two profiles, a vertical profile and an offset profile, from which the velocity of the radar signal at any point along the traverse could be calculated and from which a representative depth scale for the subsurface profile was determined. The profile results proved useful in identifying regions of massive ice in the permafrost. Logs from holes drilled for the oil pipeline's Vertical Support Members are compared with the radar profile data. This comparison shows that the radar detected the top and bottom of massive ice to a depth of approximately 30 ft.

MP 1176 RESILIENT RESPONSE OF TWO FROZEN AND THAWED SOILS.

AND IRLAWED SUILS.

Chamberlain, E.J., et al, American Society of Civil Ragineers. Geotechnical Engineering Division.

Cole, D.M., Johnson, T.C.

33-2178 SUBGRADE SOILS, SEASONAL PREEZE THAW, SOIL MECHANICS, STRESSES, LOW TEMPERA-TURE TESTS.

TURE TESTS.

Values of resilient modulus and Poisson's ratio were determined for silt and clay subgrade materials subjected to seasonal freezing and thawing. A new tachnique employing noncontacting variable impendance transducers was employed to obtain radial strain data for calculation of Poisson's ratio. The data were analyzed using multiple linear regression and analysis of variance techniques to obtain empirical relationships between the resilient moduli and Poisson's ratio parameters and stress and material property variables. Resilient modulus data ranged from over 6,000,000 psi for the frozen condition to less than 600 psi for the chawed condition. Poisson's ratio ranged from 0.07 to 0.61, the majority of the values falling between 0.03 and 0.50.

MP 1177 OXYGEN ISOTOPE INVESTIGATION OF THE ORIGIN OF THE BASAL ZONE OF THE MATA-NUSKA GLACTER, ALASKA. Lawson, D.E., et al, Journal of geology, 1978, Vol.86,

p.673-685, 34 refs. Kulla, J.B.

GLACIER ICE, ICE STRUCTURE, OXYGEN ISO-TOPES, THERMODYNAMIC PROPERTIES.

An analysis of the oxygen isotope content of ice of the englacial and basal zones of the Matanuska Glacier at its terminus reveals the origin of the ice and entrained debris. The decrease with depth in the change of 018 values of ice of the diffused facies of the englacial zone and the new occrease with depth in the change of O18 values of the dispersed facies of the basal zone is consistent with previous studies and indicates this ice originates in the accumulation area. Characteristics of the ice and debris of the dispersed facies indicate a subglacial source for most of the debris. The sharp increase of more than 4 per mill in the change of O18 values of ice of the lower, stratified facies of the basal zone and its young radiocarbon age indicate this facies formed by subglacial freezing of isotopically enriched meltwater, probably surface-derived, to the glacier sole. The bubble-poor, fine-grained ice, thickness, stratification, rounded pebbles, and undisturbed sedimentary structures in this facies support this conclusion. The location, extent, and rates of subglacial ice formation and sediment entrainment vary. The Matanuaka Glacier is therefore thermally complex, with zones of ice at the glacier sole that are at or below the pressure-melting point.

MP 1181 HYDRAULIC TRANSIENTS: A SEISMIC SOURCE IN VOLCANOES AND GLACIERS. St. Lawrence, W.F., et al, Science, Feb. 16, 1979, 203(4381), p.654-656, 10 refs. SEISMIC

WAVE PROPAGATION, GLACIERS, VOL-CANOES, EARTHQUAKES.

A source for certain low-frequency seismic waves is postulated in terms of the water hammer effect. The time-dependent displacement of a water-filled subglacial conduit is analyzed to demonstrate the nature of the source. Preliminary energy calculations and the observation of hydraulically generated seismic radiation from a dam indicate the plausibility of the proposed source.

MP 1182 TERMINAL BALLISTICS IN COLD REGIONS MATERIALS

MATERIALS.

33-2729
PROJECTILE PENETRATION, PENETRATION TESTS, FROZEN GROUND, SNOW COVER. In a winter environment, snow and frozen soil may be the most readily available materials for use in field fortifications. Design of effective fortifications requires detailed knowledge of the response of these materials to impact from projectiles and projectile fragments. Data for small arms projectile and simulated projectile fragments and projectile and simulated projectile fragments, and the prediction made using both closed form and empirical solutions are compared with test results, and the prediction techniques are discussed. Besic agreement between predicted and measured penetrations was obtained for the simulated projectile fragments, which tended to remain stable in the target materials. Penetration of 7.62 mm small arms projectiles into frozen soil targets is also predictable at velocities below about 600 m/s, above which they tend to become unstable and tumble in the target. In the case of the empirical solution, the results presented serve to extend its range of applicability to projectiles weighing less than 0.9 kg.

SPILL SENSITIVITY MAPS. Walker, D.A., et al, Arctic, Sep. 1978, 31(3), p.242-259, In English with French summary. 29 refs. Webber, P.J., Everett, K.R., Brown, J. 33-2793

OIL SPILLS, ENVIRONMENTAL IMPACT, TUNDRA VEGETATION, INDEXES (RATIOS), MAPS.

MAPS.
Crude oil was spilled on six of the major Prudhoe Bay plant communities at an intensity of 12 liters/sq m. The communities occurred along a topographic-moisture gradient. The reaction of the major species of the various communities was recorded one year following the spills. Sedges and willows showed substantial recovery from crude oil spills. Mosses, lichens, and most dicotyledons showed little or no recovery. On a very wet plot with standing water, the vegetation showed very poor recovery. Dryss integrifolis M. Vahl, the most important vascular species on dry sites, was killed. Identical experiments using diesel oil rather than crude oil showed all species except an aquatic most to be killed. A sensitivity index for the communities was calculated on the beais of the percentage cover of the resistant species divided by the original total plant cover of the community. With this information an oil spill sensitivity map for an area of Prudhoe Bay was constructed data from Prudhoe Bay together with some from the literature, a predictive sensitivity map was also constructed for an socidental crude oil spill at nearby Franklin Bluffs. In this example all the community types are considered to have moderate to excellent recovery potential.

Prudhoe Bay crude oil and refined diesel fuel were applied to five topographically distinct tundra soils at Prudhoe Bay, Alaska. The penetration of hydrocarbons into the soil column depended on soil moisture and drainage characteristics. Biodegradation, shown by changes in the pristane to heptadeone and resolvable to total gas chromatographic area ratios, appeared to be greatly restricted in drier tundra soils during one year exposure. Some light hydrocarbons were recovered from soils one year after spillages. Hydrocarbons were still present in soils at Fish Creek, Alaska, contaminated by refined oil spillages 28 years earlier, attesting to the persistence of hydrocarbons in North Slope soils.

MP 1187 STUDY OF SEVERAL PRESSURE RIDGES AND ICE ISLANDS IN THE CANADIAN BEAUFORT

Hinatiuk, I., et al, Journal of glaciology, 1978, 20(84), p.519-532, In English with French and German summaries. 3 refs. Kovacs, A., Mellor, M. 33-2885

PRESSURE RIDGES, ICE ISLANDS, ICE COVER THICKNESS, PROFILES.

THICKNESS, PROFILES.

The environmental conditions in the southern Beaufort Sea are described, with special emphasis on pressure ridges and ice islands. Techniques for determining the geometric configurations and the physical and mechanical properties of sea-ice structures and ice islands are described. Forfiles of pressure ridges were determined by surface surveys, drill-hole probes and side-looking sonar scanning. Multi-year pressure ridges with thicknesses up to 20 m and widths up to 120 m were examined in detail. The first-year ridge of 22 m thickness and 100 m width was studied. Results are given for several multi-year and the first-year ridges. Information obtained from dives under the ice is also given. Corresponding data are given for grounded in 15 m of water was one of several investigated. Measurements of temperature, salinity, tensile strength, and compressive strength are given for ice taken from old pressure ridges; and factors influencing the interpretation of test data are discussed.

FULL-DEPTH PAVEMENT CONSIDERATIONS

IN SEASONAL FROST AREAS.

33-2904 BITUMINOUS BITUMINOUS CONCRETES, SEASONAL FREEZE THAW, FROST RESISTANCE, FROST PENETRATION, SUBGRADE PREPARATION, PROST HEAVE.

FROST HEAVE.

Two full-depth pavement sections were built on highly frostsuaceptible subgrades that had been properly prepared. Suitable structural and service performances were achieved in
spite of substantial, though uniform, frost heaves. A fulldepth pavement built on a local municipal street has not
approached structural failure. However, poor service performance caused by differential heaves and severe differences
at surface castings has resulted. This paper reports on
these studies and attempts to underscore the importance
of proper design and construction of pavements on highly
frost-susceptible soils. Particular emphasis is placed on
the quality of subgrade preparation.

Finally, the incorporation of transition sections at surface castings is considered
necessary to diminish differential heave at the castings.

33-2959 ICE FOG, FOG DISPERSAL, CHEMICAL REAC-TIONS.

TIONS.

Toe fog suppression experiments on the Fort Wainwright Fower Plant cooling pond were conducted during the winter of 1974-76. Hexadecanol was added to the pond and dramatically improved visibility by reducing fog generated from water vapor released by the pond at -14C. Although this temperature was not low enough to create ice fog. the cold vapor fog created was equally as devastating to visibility in the vicinity of the pond. During the winter of 1975-76, suppression tests were continued using films of hexadecanol, mixes of hexadecanol and octadecanol, and ethylene glycol monobutyl ether (BGMB). Suppression effectiveness at colder temperatures was studied and limits to the techniques were probed. A reinforcing grid was constructed that prevented breakup of the film by wind and water currents. Lifetime tests indicated that BGMB degrades much more slowly than either hexadecanol or the hexadecanol-octadecanol mix. All the films were found to be very effective fog reducers at warmer temperatures but still allowed 20% to 40% of normal evaporation to occur. The vapor thus produced was sufficient to create some ice fog at lower temperatures, but this ice fog occurred less frequently and was more quickly dispersed than the thick fog that was present before application of the films.

ICE COVER.

Los blockage of water intake structures can pose serious threats to the availability of cooling water at thermal power plants. Ice blockage difficulties are described as they may occur in rivers, lakes, reservoirs, and estuaries, and as they may affect intakes either at the surface or submerged. Characteristics of both surface sheet ice and frazil ice are examined: formational processes, sizes, thicknesses, movement or mobility, and modes of blockage or adhesion. Case histories of incidents of ice blockage or adhesion. Case histories of incidents of ice blockage of intakes are given. Solving ice blockage problems, either through original design, post-construction modification, or revised operational techniques is discussed.

MP 1198 EFFECT OF THE OCEANIC BOUNDARY LAYER ON THE MEAN DRIPT OF PACK ICE: APPLICATION OF A SIMPLE MODEL

McPhee, M.G., Journal of physical oceanography, Mar. 1979, 9(2), p.388-400, 14 refs. For this paper from another source, see 32-4551. 33-3216

PACK ICE, DRIFT, BOUNDARY VALUE PROB-LEMS, MATHEMATICAL MODELS, ICE WATER INTERFACE.

WATER INTERFACE.

Smoothed records of ice drift, surface wind and upper ocean currents at four manned stations of the 1975-76 AIDJEX experiment in the central Arctic have been analyzed to provide a statistical relationship between stress at the ice-cean interface and ice-drift velocity during a 60-day period when the ice was too weak to support internal forces. Resential features of the model are dynamic scaling for velocity, kinematic stress and length, with exponential attenuation of a linear dimensionaless eddy viscosity. Currents measured 2 m below the ice confirmed the shape of the stress vs ice speed curve and provided an estimate of the angle between surface stress and velocity. The model was used to qualitatively estimate the effect of a pycnocline at 25 m on surface characteristics. The observed behavior when stratification at that level was most pronounced tended toward slightly higher drag at higher speeds, which is qualitatively consistent with the model results.

ICE CORES, ULTRASONIC TESTS, ICE CRYSTAL STRUCTURE, ANTARCTICA—BYRD STA-TION.

This report discusses some results of recent measurements of ultrasonic velocities performed on ice cores collected in 1968 at Byrd Station. The analytical technique is described it is concluded that measurement of ultrasonic velocities

of cores from deep drill holes enables monitoring of the relation characteristics of the cores and determination of the gross trends of c-axis orientation in the ice sheet. Supplemented by optical thin section, studies can verify the exact nature of the fabric at any given depth and any inclination of the fabric symmetry axis with respect to the direction of propagation of P-wave velocity.

MP 1203 SEA ICE AND ICE ALGAE RELATIONSHIPS IN THE WEDDELL SEA.

Ackley, S.P., et al, Antarctic journal of the United States, Oct. 1978, 13(4), p.70-71, 7 refs. Taguchi, S., Buck, K.R.

33-3363 SEA ICE, PACK ICE, ALGAE, CRYOBIOLOGY, ICE BREAKUP, CHEMICAL COMPOSITION, WEDDELL SEA.

Analysis of data obtained during a 1977 cruise in the Weddell Sea indicates that the ice algal community found during that cruise is distinct from others that have been described sea minimizes that he to easily community toward unring that cruise is distinct from others that have been described (for example, the bottom epontic communities in the landstatic in McMurdo Sound, the surface communities off East Antarctics, and the bottom communities in Arctic Pack icc.) Unlike these other communities, the Weddell pack algae is dominantly an interior one, existing not at the surface or bottom but at mid-depth (65 to 2.15 m) within the icc. The formation of this community is dependent on the unique thermal and physical setting for Weddell pack icc. Brine drainage processes are initiated by summer warming, but are not carried through to completion as in the Arctic. This process causes a redistribution of salinity, maximizing in the mid-depth regions of the ice and apparently leading to algae production because of the relatively higher nutrient levels at those mid-depth. A qualitative model indicating the relationship between the thermally induced brine migration and subsequent algae growth is given.

MENT.

Observations include determinations of subsea sediment temperature, type, ice content, and chemical composition. These data, coupled with geophysical studies and results from other Beautort Ses geological studies, are being used jointly to ascertain subsea permafrost distribution. This report includes a summary of the spring 1977 field program and a general summation of the results from two years of field study in the Prudhoe Bay area. The 1977 field study produced six additional drilled and sampled holes plus 27 probe sites which yielded both material property and temperature data. The field observations and the results of laboratory analyses of the samples help to demonstrate the complex nature of subsea permafrost.

FROZEN GROUND PHYSICS, UNFROZEN WATER CONTENT, NUCLEAR MAGNETIC RESONANCE, SOIL CHEMISTRY, SALINE SOILS.

SOILS.

A simple, rapid method of determining the unfrozen water content of frozen soils is described in detail. The method uses the first pulse simplitude of a pulsed nuclear magnetic resonance analyzer. Phase composition curves were obtained for four soils at very high total water contents. Three of the soils (Manchester fine sand, Rairbanks silt, and Goodrich clay) had been previously examined by another method (sothermal calorimeter). The fourth (Kotzebue silt) is a naturally saline soil found in low-lying coastal regions of Alaska. This soil was tested both in its natural state and with the soluble salts removed. The phase composition curves obtained by the nuclear magnetic resonance method are consistent with those obtained by using the isothermal calorimeter, but the nuclear magnetic resonance method aved time, requiring only 48h. It also provides a high degree of reproducibility and can be used over a wide range of temperatures. As expected, the unfrozen water content of the saline soil was much higher in its natural state than after removal of the soluble salts. In addition, the unfrozen water content of all four soils appears to increase somewhat as the total water content of the sample is increased.

Munis, R.H., Marshall, S.J., Greatorex, A. 33-3735

BUILDINGS, HEAT LOSS, TEMPERATURE

MEASUREMENT, TESTS. A two-stage program for determining the applicability of various remote thermal scanning systems for detecting heat losses in buildings is described. The types of instruments tested are high resolution thermal imaging systems, low resolution thermal imaging systems, thermal line scanners and point radiometers. The first phase of this project consisted of inserting known building defects into a specially designed room at the USA Cold Regions Research and Engineering Laboratory and having a representative of the manufacturer of each type of equipment inspect the room at three temperature differences across the room envelone. The second obase of each type of equipment inspect the room at three temperature differences across the room envelope. The second phase of this project will consist of a field evaluation of these same instruments in approximately 10 cities, in cooperation with a weatherization program for low-income housing sponsored by the Community Services Administration and directed by the National Bureau of Standards. The goal of the second phase is to determine the cost effectiveness of various remote thermal scanning services.

DETECTING WET ROOF INSULATION WITH A HAND-HELD INFRARED CAMERA.

33-3736

INFRARED PHOTOGRAPHY, ROOFS, MOISTURE, DETECTION.

TURE, DETECTION.

Since 1975, CRREL has used hand-held infrared scanners for detecting wet insulation under built-up roof membranes. Thermocouples installed on roofs have shown that temperature differences between areas of wet and dry insulation may exist during both the day and night. The optimum time to detect these differences with an infrared camera is at night when solar interference is eliminated. Surveys have been conducted successfully in many locations from Alabams to Alaska during both warm and cold weather. Three-inch diameter core samples of the roof membrane and insulation have been obtained to verify infrared findings. This paper briefly overviews the technique used to survey roofs for moisture and then presents results of a controlled experiment at Pease. AFB, New Hampshire, to show the correlation between thermal images and temperature differences observed thermoelectrically in wer and dry portions of a roof. Measurements of the thermal resistance of the wet and dry areas complete the physical picture.

REMOTE DETECTION OF WATER UNDER ICE-COVERED LAKES ON THE NORTH SLOPE OF ALASKA.

Kovacs, A., Arctic, Dec. 1978, 31(4), p.448-458, 9

33-3773

REMOTE SENSING, LAKE WATER, LAKE ICE, RADAR ECHOES, ICE COVER THICKNESS, WATER SUPPLY.

RESULE From using an impulse radar sounding system on the North Slope of Alaska to detect the existence of water under take ice are presented. It was found that both lake ice thickness and depth of water under the ice could be determined when the radar antenna was either on the ice surface or sirborne in a helicopter. The findings also revealed that the impulse radar sounding system could detect where lake ice was bottom-fast and where water existed under the ice cover.

MELTWATER, SNOW COVER STRUCTURE, WATER FLOW, SNOW STRATIGRAPHY, CAPILLARITY, SURFACE WATERS.

An earlier gravity flow theory (Colbeck 1971) treated snow as a homogeneous and uniform medium. The theory is expanded here to include the effects of ice layers and flow channels. Two examples are constructed and compared with observed runoff. In this particular situation, the results suggest that most of the water moves down flow channels.

CONCRETE PAVEMENTS, ICE REMOVAL, AN-TIFREEZES, TESTS.

TIPRBECES, TESTS.

The extent of deterioration of portland cement concrete and several types of asphaltic concrete subjected to organic deicing chemicals was determined over 60 freezing-thawing cycles. Proprietary solutions containing ures, ethylene glycol, and formamide affected the surface of old sir-entrained concrete only slightly (rating of 1 on a scale of 0 to 5 of increasing degradation). Asphaltic concrete specimens were not significantly affected. Abrasion tests were made on air-entrained concrete specimens exposed to ethylene glycol solution during freezing and thawing; material loss was very low, nearly the same as with a distilled water control.

MAPPING.

The objectives of the work described in this report were to use and evaluate new radiowave methods of measuring earth resistivity in the LF and VLF bands and to develop estimated effective ground resistivity maps in this same band for the United States, including Alaska. Both airborne and ground methods were investigated by using the wavetilt and surface impedance techniques. It is concluded from the VLF study that over much of the central United States VLF airborne resistivity might well approximate LF ground resistivity. The ground methods discussion concerns the surface impedance method in the LF band. It is concluded from the LF studies that the present conductivity map is fairly accurate for BCB purposes but inapplicable to LF purposes.

MODELS.

The findings of a field study designed to generate fundamental data on multi-year pressure ridges in the near shore zone of the Canadian Beaufort Sea are presented. The study investigated the geometry of eleven floating multi-year ridges or ridge fragments and the sail height and keel depth of four additional multi-year ridge fragments. The cross-sections of multi-year ridges fragments. The cross-sections of multi-year ridges fragments. The cross-sections of multi-year ridges with total thicknesses varying between 9.6 and 41.8 m were examined, and the results suggest that they can be adequately represented by one ridge model with a constant sail to keel ratio and geometry. It is also shown that the ice comprising multi-year ridges is solid with the interblock voids existing at the time of their formation being completely filled with ice. The data obtained from this study are being used in the engineering design of exploration and production systems for the Beaufort Sea. In the shallow waters of this area, exploratory drilling from artificial islands has been carried out since 1973, and since 1976, the exploration effort has extended into the deeper waters of the Beaufort Sea, using drillships.

MP 1230 ICE PILE-UP AND RIDE-UP ON ARCTIC AND SUBARCTIC BEACHES.

Kovacs, A., et al, International Conference on Port and Ocean Engineering Under Arctic Conditions, 5th, Trondheim, Norway, Aug. 13-18, 1979. Proceed-ings, Vol.1, Trondheim, University, 1979, p.127-146, 22 refs.

Sodhi, D.S. 33-4610

SEA ICE, SHORES, PRESSURE RIDGES, ICE PUSH.

PUSH.

Information on ahore ice pile-up and ride-up in arctic and subarctic waters is presented.

Cross-sectional profiles of several ice pile-ups and ride-ups are presented from which models and theoretical analyses were made. The expressions derived give the force required to overcome gravitational potential and friction occurring during ice-piling and ride-up. It was estimated that the distributed force required during ice-piling or ride-up was of the order of 10 to 350 kPa (about 1.5 to 50 pa). Field observations revealed that shore ice pile-up or ride-up appears to occur within a period of less than 30 minutes at any time of year, but most often in the spring and fall. Pile-up seldom occurs more than 10 m inland from the sea, but ride-up frequently extends 50 m or more inland, regardless of ice thickness. While steeply aloging shores do not favor ice ride-up, sea ice has mounted the steep, 9-m-high bluff at Barrow, Alaska, destroying structures and taking lives.

TEMPERATURE EFFECT ON THE UNIAXIAL STRENGTH OF ICE.

Haynes, F.D., International Conference on Port and Ocean Engineering Under Arctic Conditions, 5th, Trondheim, Norway, Aug. 13-18, 1979. Proceedings, Vol.1, Trondheim, University, 1979, p.667-681, 17 refs 33-4632

ICE STRENGTH, COMPRESSIVE STRENGTH, TENSILE PROPERTIES.

TENSILE PROPERTIES.

The effect of temperature on the uniaxial strength of finegrained, polycrystalline ice was investigated. Dumbbellshaped specimens were loaded in uniaxial compression and
uniaxial tension. Two machine speech, 0.847 mm/s and
84.7 mm/s, were used for the tests, and the test temperatures
ranged from -0.1 to -54C. The uniaxial compressive strength
is very sensitive to temperature, generally increasing as the
temperature decreased from -0.1C to -54C, with the greatest
is very sensitive to temperature, but did continue to
increase with decreasing temperature. Tensile strength
also increased the most between -0.1C and -3C. An initial
tangent modulus and a 50% stress modulus were found
for each compression test. The initial tangent modulus
increased about two times as the temperature decreased
with decreasing temperature. A secant modulus was found
for the tensile tests and it tended to decrease with decreasing
temperature. The specific energy required to cause failure
was also found for the compression and tension tests.

BUCKLING ANALYSIS OF WEDGE-SHAPED PLOATING ICE SHEETS.

WET SNOW, SNOW COMPACTION, SNOW RE-MOVAL, SALINITY.

MOVAL, SALINITY.

The compressibility of wet snow decreases with decreasing liquid water content but increases with decreasing salinity. Also, the tendency for snow splashing on highways increases with decreasing salinity. These opposite effects are complicated by the fact that liquid water content and salinity are not necessarily independent. The amount of liquid present can be controlled somewhat by the road grade, and salinity is generally determined by how much salt is applied to the road surface. For different situations it may be desirable to regulate salt applications in order to achieve a maximum amount of splashing with a minimum of compaction of wet snow into ice. Here we provide a qualitative review of wet snow and suggest how an understanding of wet snow's behavior on a road surface might increase our ability to deal with snow removal problems.

Buck, K.R., Taguchi, S. 33-4674

SEA ICE, ALGAE, CRYOBIOLOGY, WEDDELL SEA.

Physical and biological measurements were made of sea ice cores taken from 69 to 78 S in the Weddell Sea. Fluores-

cence measurements indicated an algal community that was strongly associated with salinity maxima within the ice. Maximum concentrations of chlorophyll a ranged from 0.3 in the 4.54 mg cu m. Comparisons with standing crops in the water column indicate that the standing crop within the ice can represent a minor but significant fraction of the total standing crop for the region. The sea ice algal community is apparently distinct from others that have been described for land-fast ice in McMurdo Sound, sea ice in the Arctic, and pack ice off East Antarctica. The highest concentrations of biological material are found in the bottom or top samples from those regions, whereas the Weddell Sea maxima are concentrated at intermediate depths (0.65 to 2.15m) within the ice. A qualitative model indicating the relationship between thermally induced brine migration and subsequent algal growth is presented. (Auth. mod.)

SNOW DEFORMATION, SNOW COVER STRUC-TURE, SNOW ACOUSTICS, ACOUSTIC MEASUREMENT, MODELS.

UREMEN I, MODELS.

The pattern of acoustic emission response in snow subjected to constant deformation rates is examined. The structural character of snow is discussed, and an equation that describes the pattern of the acoustic emission response is derived. Comparison between the predicted acoustic response and experimental data is made and the agreement is shown to be excellent. The acoustic emission response for 7075-T6 aluminum and iron-3% silicon subjected to constant rates of deformation is also considered. The acoustic emission equation derived for anow represents the response in these materials. It is suggested that the internal fracture concept used to develop the model for snow may also apply to used to develop the model for snow may also apply to other densely packed polycrystalline materials. to develop

MP 1247 DYNAMIC THERMODYNAMIC SEA ICE MOD-

Hibler, W.D., III, Journal of physical oceanography, July 1979, 9(4), p.815-846, 51 refs.

SEA ICE, THERMODYNAMICS, HEAT TRANS-FER, ICE COVER THICKNESS, MATHEMATI-CAL MODELS.

A numerical model for the simulation of sea ice circulation and thickness over a seasonal cycle is presented. This model is used to investigate the effects of ice dynamics on arctic ice thickness and sir-sea heat flux characteristics on arctic ice thickness and air-sea heat flux characteristics by carrying out several numerical simulations over the entire Arctic Ocean region. The essential idea in the model is to couple the dynamics to the ice thickness characteristics by allowing the ice interaction to become stronger as the ice becomes thicker and/or contains a lower areal percentage of thin ice. The dynamics, in turn, causes high oceanic heat losses in regions of ice divergence and reduced heat losses in regions of convergence. To model these effects consistently, the ice is considered to interact in a plastic manner with the plastic strength chosen to depend on the ice thickness and concentration. The thickness and concentration, in turn, evolve scoording to continuity equations which include changes in ice mass and percent of open water due to advection, ice deformation and thermodynamic

MP 1248 STEADY IN-PLANE DEFORMATION OF NON-COAXIAL PLASTIC SOIL.

Takagi, S., International journal of engineering acience, 1979, Vol.17, p.1049-1072, 27 refs. 34-860

SOIL CREEP, PLASTIC PROPERTIES, THEORIES, BOUNDARY VALUE PROBLEMS, ANALYSIS (MATHEMATICS).

YSIS (MATHEMATICS).

Presented in this paper is the theory of the steady inplane deformation, obeying the Coulomb yield criterion, of
plastic soils whose strain rate and stress principal directions
are noncoaxial. The constitutive equations including an
unknown noncoaxial angle are derived by use of the geometry
of the Mohr circle and the theory of characteristic lines.
A boundary value problem is solved by assigning to the
non coaxial angle a set of such values that enable us to
accommodate the presupposed type of flow satisfying the
given boundary conditions in a given domain. The plastic
material regulated by the Coulomb yield criterion in inplane deformation is, therefore, a singular material whose
constitutive equations are not constant with material but
are variable with flow conditions.

ANISOTROPIC PROPERTIES OF SEA ICE IN THE 50- TO 150-MHZ RANGE.

Kovaca, A., et al. Journal of geophysical research, Sep. 20, 1979, 84(C9), p.5749-5759, 4 refs. Morey, R.M. 34-963

SEA ICE, RADAR ECHOES, ICE CRYSTAL STRUCTURE, OCEAN CURRENTS, DIELECTRIC PROPERTIES, ANISOTROPY.

TRIC PROPERTIES, ANISOTROPY.

Results of impulse radar studies of sea ice near Prudhoe Bay, Alaska, show that where there is a preferred current direction under the ice cover, the crystal structure of the ice becomes highly ordered. This includes a crystal structure with a preferred borizontal c axis that is oriented parallel with the local current. The radar studies show that this structure behaves as an anisotropic dielectric. The result is that when electromagnetic energy is radiated from a dipole antenna in which the E field is oriented perpendicular to the c axis aximuth, no bottom reflection is detected. It was also found that the frequency dispersion of anisotropic sea ice varies in the borizontal plane. This is demonstrated by the center frequency of the reflected signal spectrum, which is maximum in the preferred c axis direction and minimum perpendicular to it. In addition, it was found that the frequency dispersion is related to the average bulk brine volume of the ice but that the bulk dielectric constant of the ice, as determined from impulse travel time, shows little correlation with the coefficient of anisotropy.

SOIL WATER MIGRATION, HEAT TRANSFER. This paper presents a set of partial differential equations that describes the concurrent one-dimensional flow of liquid and heat in unfrozen unasturated soils. A Galerkin finite element method based on hermite polynomials was used to solve the equations numerically. To verify both the theory and the solution method, laboratory measurements were made on a horizontal soil column. The results furnished essential transport coefficient values, as well as data records over space and time for infiltrations of cold water that produced steep, interacting temperature and moisture content gradients. Comparison of measured and predicted values showed very good agreement in both the moisture and temperature domains. Contrary to the usual assumption in soil studies, liquid convection played a large role in the heat transfer. A simple geometric mean formula represented the soil thermal conductivity quite adequately. SOIL WATER MIGRATION, HEAT TRANSFER.

MP 1260 SURFACE-BASED SCATTEROMETER RE-SULTS OF ARCTIC SEA ICE.

Onstott, R.G., et al, IEEE transactions of geoscience electronics, July 1979, GE-17(3), p.78-85, 16 refs. Moore, R.K., Weeks, W.F. 34-1167

SEA ICE, RADAR ECHOES, BACKSCATTER-ING, PRESSURE RIDGES, ICE COVER THICK-

dar backscatter measurements were made of shorefast sea near Point Barrow, AK, in May 1977, with a surface-Radar be

based FM-CW scatterometer that swept from 1-2 GHz and from 8.5-17.5 GHz. The 1-2 GHz measurements showed that thick first-year and multiyear ice cannot be distinguished at 10-70 deg incidence angles but that undeformed sea ice can be discriminated from pressure ridges and lake ice. Results also indicate that frequencies between 8-18 GHz have the shility to discriminate between thick first-year, multiyear, and lake ice. Cross polarization was found to be a better discriminator than like polarization. In addition, at these latter frequencies the differential scattering was found to have an approximately linearly increasing frequency response. cy respon

WET SNOW, SNOW CRYSTAL STRUCTURE, GRAIN SIZE, BOUNDARY VALUE PROBLEMS, SNOW PHYSICS.

The grain boundaries in snow are generally unstable when the pore space is filled with liquid water (i.e., liquid-saturated snow). Thus, when unstressed snow is saturated with the melt, the ice particles in snow are cohesionless spheres. This leads to very low arengths and to rapid grain growth due to heat flow among particles of different sizes. The grain boundaries in highly unsaturated snow (up to about 7% liquid by volume) with small applied loads are stable,

and the grains must be arranged in clusters to achieve local force equilibrium. Two grains bond together with geometrical constraints on the radii of the phase boundaries. Three grains join at a liquid vein whose size is determined by grain size and capillary pressure (i.e., liquid "tension"). Slow grain growth occurs by sublimation, vapor diffusion, and condensation, and intergrain strength is relatively high. Once grain clusters are formed, equilibrium imposes constraints on the curvature of the phase boundaries which limit change in the carellary pressure. in the capillary pressure.

WATER CHEMISTRY, GASES, VAPOR TRANS-FER, POLLUTION, LABORATORIES.

FER, POLLUTION, LABORATORIES.

The passage of mercury vapor from ambient air through the walls of conventional polyethylene (CPB), linear polyethylene (LPE), and Teflon (FEP) containers can seriously contaminate solutions of distilled and natural water stored in these containers. The rate of mercury contamination is dramatically increased when the sample solution contains oxidizing agents such as nitric acid or potassium permanganate, which are commonly used as preservatives to prevent loss of mercury (II) ion. The rate of contamination also depends on container material and decreases in the order CPE> LPE> FEP> glass. Preezing the samples in plastic containers is an effective way to prevent mercury contamination. When freezing is not practical, storage in glass containers minimizes sample contamination from ambient mercury vapor.

CORRELATION AND QUANTIFICATION OF AIRBORNE SPECTROMETER DATA TO TURBIDITY MEASUREMENTS AT LAKE POWELL, UTAH.

Метту, С. J., International Symposium on Remote Sensing of Environment, 13th, Ann Arbor, Michigan, April 23-27, 1979. Proceedings, Environmental Research Institute of Michigan, 1979, p.1309-1316, 7 refs.

34-2043 LAKE WATER, TURBIDITY, SUSPENDED SEDI-MENTS, LIGHT TRANSMISSION, AERIAL SUR-VEYS, SPECTROSCOPY.

VEYS, SPECTROSCOPY.

A water sampling program was accomplished at Lake Powell, Utah, during June 1975 for correlation to multispectral data obtained with a 500-channel airborne spectroradiometer. Field measurements were taken of percentage of light transmittance, surface temperature, pH and Seechi disk depth. Percentage of light transmittance was also measured in the laboratory for the water samples. Analyses of electron micrographs and suspended sediment concentration data for four water samples located at Hite Bridge, Mile 150 and Bullfrog Bay indicated differences in the composition and concentration of the particulate matter. Airborne spectrors/diometer multispectral data were analyzed for the four sampling locations. The results showed that: (a) as the percentage of light transmittance of the water samples decreased, the reflected radiance increased; and (b) as the suspended sediment concentration (mg/1) increased, the reflected radiance increased in the 1-80 mg/1 range. In conclusion, valuable qualitative information was obtained on surface turbidity for the Lake Powell water spectra. Also, the reflected radiance measured at a wavelength of 0.58

micron was directly correlated to the suspended acdiment

THAW CYCLES.

Cores from the bottom 4.83 m of the antarctic ice sheet at Byrd Station contain abundant stratified debris ranging from silt-sized particles to cobbles. The nature and disposition of the debris, together with measurements of the physical properties of the inclosing ice, indicate that this zone of diri-taden ice originated by "freezing-in" at the base of the ice sheet. The transition from air-rich glacial ice to ice practically devoid of air coincided precisely with the first appearance of debris in the ice at 4.83 m above the bed. Stable-isotope studies made in conjunction with gas-content measurements also confirm the idea of incorporation of basal ice may well constitute the most diagnostic test for discriminating between debris incorporated in a meltitude of the company of the confirmation of basal between debris incorporated in a meltitude of the company of the confirmation of the company of the confirmation of the company of the confirmation of the company of the company of the confirmation of the company of the company of the confirmation of the company of the comp tion of basal ice may well constitute the most diagnostic test for discriminating between debris incorporated in a meli-refreeze process and debris entrapped by purely mechanical means, e.g. shearing. We conclude from our observations on bottom cores from Byrd Station that "freezing-in" of basal debris is the major mechanism by which sediment is incorporated into polar ice sheets. (Auth.) MP 1273

WATERSHEDS, DRAINAGE, STREAM FLOW.

WATERSHEDS, DRAINAGE, STREAM FLOW. A drainage network map of the Caribou-Poker Creek Research Watershed, near Fairbanks, Alaska, has been used to conduct a Strahler stream order analysis and an analysis of length distributions of source and tributary-source links in a subarctic watershed. The basins have very low drainage densities, ranging from 1.35 km/sq km to 5.34 km/sq km. Bifurcation ratios were higher than those found in watersheds in the continental U.S. Statistical analysis indicates that source and tributary-source links in a subarctic watershed belong to different length populations, the same as found in other regions of the world. Additional analysis indicates that exterior links originating on permafrost slopes tend to be shorter than those originating on non-permafrost (well-drained) slopes.

HIGH-FORCE TOWING.

Mellor, M., Cold regions science and technology, Feb. 1980, 1(3/4), p.231-240, 5 refs.

ICEBERG TOWING, LOADS (FORCES).

ICEBERG TOWING, LOADS (FORCES). Required force levels for iceberg towing at 1 knot could be at least 50 tons for protection of structures and drillships in northern waters, and around 1000 tons for iceberg exports from the Antarctic. Corresponding values of effective ("towope") power are only 307 hp and 6140 hp, respectively. A conventional-hull supertug capable of 1000 tons thrust would probably have T/P = 10 10 10/hp, p=200,000 hp, and a propulsive efficiency of about 3%. The most practical expedient for sustractic towing seems to be use of multiple conventional tugs, with fewer tugs or higher speeds as the iceberg reduces its size and streamlines itself. The practical difficulty of towing antarctic icebergs may have been underestimated, and it might be worth reconsidering preliminary shaping of the iceberg to reduce the drag. (Auth.)

COMPARISON OF THE PEBBLE ORIENTA-TION IN ICE AND DEPOSITS OF THE MATA-NUSKA GLACIER, ALASKA.

Lawson, D.E., Journal of geology, Nov. 1979, 87(6), p.629-645, 21 refs. 34-2502

GLACIAL DEPOSITS, ICE STRUCTURE, SEDI-MENT TRANSPORT.

Depositional processes and their sediment source determine the orientation of pebbles in the deposits of the Matanuska

Chacier and the relationship of this orientation to the direction of ice flow. Pebble fabrics in ice-derived deposits differ from those in resedimented deposits: fabric in deposits from sediment flow, ablation of exposed basal zone ice, and the slumping and spalling of ice-cored slopes does not correspond to the ice flow direction, but is developed by these depositional processes. Pebbles in basal ice and melt-out till show a unimodal distribution of orientations, with individual observations only slightly discrepted about the mean axis. Pebble a mimodal distribution of orientations, with individual observations only slightly dispersed about the mean axis. Pebble fabrics in other deposits are polymodal, with a significantly larger amount of dispersion about the mean axis. The regional pattern of mean axes of basal zone ice and meltiout till pebble fabrics approximates the local and regional trends of ice flow, but pebble imbrication in ice and sediment does not necessarily indicate the direction from which the glacker flowed. A small number of measurements of pebble orientations at many sites and the analysis of these data by the eigenvalue method appear to be suitable techniques for examining the pebble fabric of glacial deposits, but additional sedimentological data are needed to define the origins of these deposits.

34-2671

SEA ICE, ICE PHYSICS, ICE CRYSTAL STRUC-TURE, OCEAN CURRENTS.

TURE, OCEAN CURRENTS.
Field observations at 60 sites located in the fast or nearfast ice along a 1200-km stretch of the north coast of Alaska between the Bering Strait and Barter Island have shown that 95% of the ice samples exhibit striking c axis alignments within the horizontal plane. In all cases the degree of preferred orientation increased with depth in the ice. Representative standard devisitions around a mean direction in the horizontal plane are commonly less than 10 deg for samples collected near the bottom of the ice. The general patterns of the alignments support the correlation between the preferred c axis direction and the current direction at the ice/water interface suggested by Weeks and Gow (1978). A comparison between c axis alignments and instantanceous current measurements made at 42 locations shows that the most frequent current direction coincides with mean c axis direction. The c axis alignments are believed to be the result of geometric selection, with the most favored orientation being that in which the current flows normal to the (0001) plates of ice that comprise the dendritic sea ice/seawater interface.

MP 1278 TRAVELING WAVE SOLUTIONS OF SATURAT-ED-UNSATURATED FLOW THROUGH POR-

OUS MEDIA.
Nakano, Y. Water resources research, Feb. 16, 1980, 16(1), p.117-122, 9 refs.
34-2672

WAVE PROPAGATION, WATER FLOW.

Traveling wave solutions to the problem of saturated-unsaturated flow of water through a uniform porous medium are derived, and the regularity properties of the solutions are studied. It is found that a singularity occurs in the higher-order derivatives of flux with respect to the space coordinate in the solutions at water tables and that the water tables can be generally interpreted as propagating acceleration waves of the *n*th order, where *n* is a positive integer.

PILOT SCALE STUDY OF OVERLAND FLOW LAND TREATMENT IN COLD CLIMATES. Jenkins, T.F., et al, *Progress in water technology*, 1979, 11(4/5), p.207-214, 11 refs.

Martel, C.J. 34-2673

WASTE TREATMENT, WATER CHEMISTRY, IRRIGATION, COLD WEATHER TESTS.

IRRIGATION, COLD WEATHER TESTS.

Primary and secondary wastewaters were applied to separate sections of an overland flow site. The dimensions of each section were 3 m in width by 30 m in length and the system was graded to a five percent slope. The site was planted with orchard grass and tall feacue. A one-year acclimation period was allowed to obtain a good cover onset of the study to establish a high level of microbial activity. Applied wastewater as well as surface and subsurface flows were monitored for NO-3, NH+4, TKN, BOD, suspended solids, pH, conductivity, and total phosphorus. The results indicate excellent warm weather performance for removal of oxygen demanding substances, suspended solids remained high throughout the winter while treatment of SOD declined to unacceptable levels at soil temperatures below 4C. Nitrogen treatment efficiency of suspended solids remained high throughout the winter while treatment of SOD declined to unacceptable levels at soil temperatures below 4C. Nitrogen treatment declined rapidly below 14C. The form of airogen applied to overland flow was found to affect performance with nitrate being the less desirable form. Phosphorus treatment by overland flow was found to be shout 80% in the summer months, declining to nil during the winter.

Delaney, A.J. 34-2674

RADIO WAVES, WAVE PROPAGATION, RADIO COMMUNICATION.

Measurements of apparent resistivity and phase derived from the complex surface impedance of radio waves propagating in the ground wave mode at frequencies in the radio navigational aid band (between 257 and 382 kHz) are presented. Areas encompassing between 400 and 800 aq km that covered a variety of glacial sediments, land forms, and some crystalline bedrock types were surveyed. The degree of dispersion found in resistivity values reflects the dispersion in grain size, while the average resistivity increases with mean grain size, while the average resistivity increases with mean grain size. size. Dielectric properties are suggested as one cause of the low phases observed over crystalline bedrock. The combination of apparent resistivity and phase data implies that the resistivity measurements are consistent in about 50% of the areas with previous measurements of field strength attenuation performed in the AM broadcast band.

Kohnen, H.

ICE SHEETS, ICE MECHANICS, DRILL CORE ANALYSIS, RELAXATION (MECHANICS), UL-TRASONIC TESTS, ANTARCTICA—BYRD STA-TION.

TION.

Deep corea from Byrd Station were used to calibrate an ultrasonic technique of evaluating crystal anisotropy in the antarctic ice sheet. Velocities measured parallel and perpendicular to the vertical axis of the cores yielded data in excellent agreement with the observed c-axis fabric profile and with the in-situ P-wave velocity profile measured parallel to the bore-hole axis by Bentley. Velocity differences in excess of 140 m/s for cores from below 1,300 m attest to the tight clustering of c axes of crystals about the vertical, especially in the zone 1,300-1,800 m. A small but significant decline in vertical velocity with ageing of the core, as deduced from Bentley's down-hole data, is attributed to the formation of oriented cracks that occur in the ice cores as they relax from environmental stresses. This investigation of cores from the 2,164 m thick ice sheet at Byrd Station establishes the ultrasonic technique as a viable method of monitoring relaxation characteristics of drilled cores and for determining the gross trends of c axis orientation in ice sheets. The Byrd Station data, in conjunction with Barkov's investigation of deep cores from Vostok, East Antarctica, also indicate that crystal anisotropy in the antarctic ice sheet is dominated by a clustering of c-axis about a vertical symmetry axis. RADAR ECHOES, FROZEN LAKES, BACK-SCATTERING, REMOTE SENSING, BUBBLES, ICE_WATER INTERFACE, ICE SOLID INTER-FACE.

FACE.

L-band radar images of a number of ice-covered lakes located approx 48 km northwest of Bethel, Alaska, show large differences in radar backscatter with lakes showing homogeneous low-returns, homogeneous high-returns and/or low-returns around the lake borders and high-returns from the central areas. The patterns of the returns suggest that a low-return indicates that the lake is frozen completely to its bottom, while a high-return indicates the presence of freshwater between the ice cover and the lake bod. This interpretation is in good agreement with the limited information available on lake depths in the study area and recent X-band radar observations of North Slope lakes by Sellman, Weeks and Campbell, who suggested such an interpretation. These effects are, however, more striking in the L-band than in the X-band imagery. This can be explained by the fact that volume inhomogeneities, such as air bubbles, will cause more activering and conductivity losses and thus more attenuation at the shorter wavelengths (X-band, 3 cm).

WATER MOVEMENT IN A LAND TREATMENT SYSTEM OF WASTEWATER BY OVERLAND FLOW.

Nakano, Y., et al, *Progress in water technology*, 1979, 11(4/5), p.185-206, 15 refs. Khalid, R.A., Patrick, W.H., Jr.

34-3949

WATER FLOW, WASTE TREATMENT, WATER TREATMENT, SOIL WATER, SATURATION, SEEPAGE, SLOPE ORIENTATION, EX-PERIMENTATION.

Water movement in an overland-flow land treatment system was studied experimentally and theoretically. A small-scale physical model was used to obtain experimental data. The theoretical analysis was based upon the shallow water equation for overland flow and the Darcy-Richards law for soil water flow. It was found that the water movement in the swater was remarkly overland by the application soil water flow. It was found that the water movement in the system was primarily controlled by the application rate, the friction slope, the slope angle, the hydraulic characteristics of soils, and the evapotranspiration. An approximate analytical solution to steady flow in the system was obtained. It was found that the rate of soil water flow was mainly determined by the saturated conductivity of soils and in less extent by the friction slope and the slope angle in the steady condition. A finite difference solution to non-steady flow was found satisfactory in simulating the experimental data.

MASS-BALANCE ASPECTS OF WEDDELL SEA

PACK-ICE.

Ackley, S.F., Journal of glaciology, 1979, 24(90), p.391-405, In English with French and German summaries. 20 refs.

SEA ICE DISTRIBUTION, MASS BALANCE, ICE DEFORMATION, SALINITY, WEDDELL SEA.

DEFORMATION, SALINITY, WEDDELL SEA.

The Weddell Sea pack ice undergoes several unique advanceretreat characteristics related to the clockwise transport in
the Weddell Gyre, the physical setting for the pack ice,
and the free boundary with the oceans to the north. From
satellite-derived ice charts, the annual cycle of the pack
ice advance and retreat is depicted. The Weddell pack
advance is characterized by a strong east-moving component
as well as the north advance seen in other regions such
as East Antarctics. Physical characteristics of the pack
ice at the summer minimum ice edge are presented. Indications are that deformation is a significant component of
the ice accumulation, deformed ice accounting for c. 15
to 20% of the area covered in the year-round pack. Ablation the ice accumulation, deformed ice accounting for c. 15 to 20% of the area covered in the year-round pack. Ablation characteristics are inferred from observations made during field work and from satellite imagery. These observations indicate that surface-melt ablation typically seen on Arctic pack is not seen on the Weddell pack inside the summer edge. Using the physical-property data and transport inferred from ship and iceberg drifts, a new annual ice accumulation > 3 m is inferred over the continental shelf in the South compared to <2 m previously estimated. The implication is the set of the continental shelf in the south compared to <2 m previously estimated. south compared to <2 m previously estimated. The implica-tion is that salt flux into the ocean over the shelf may be significantly larger, thereby increasing the production of Western Shelf Water, a component of Antarctic Bottom Water. (Auth.) The objective of CRREL's subsea permafrost program is to obtain information on the distribution and properties of permafrost beneath the Besufort Sea. We are currently acquiring information on the distribution of ice-bunded permafrost from analysis of the velocity structure of commercial seismic records. This report summarizes the results of all studies to date, including engineering property analysis and preliminary interpretation of seismic data. Emphasis is placed on results that are relevant to offshore development of this region.

Discussion of the CRREL drilling and laboratory program represents the most current interpretation of these data.

The object of the CREEL study is to: (a) determine the cause of the significant relief which exists under the fast ice, (b) measure the variations in the relief under fast ice, using electromagnetic echo sounding, (c) determine if the under-ice relief is: series of individual pockets or consists of long rills, (d) estimate the quantity of oil which could pool up in the under-ice depressions should oil be released under the ice cover (c) use impulse radar to study the electromagnetic properties and anisotropy of sea ice. Initial results from using a polarized redar antenna in the air from the NOAA helicopter indicate that the c-axis anisotropy can be determined from the sir. Because this anisotropy is related to current direction, it should be possible to measure, from an airborne platform, the current direction at the ice/water interface.

lee sheets are inhomogeneous; properties vary strongly with depth. Theoretical treatment of plates with properties varying perpendicular to the plate has now been satisfactorily developed for floating ice sheets.

However, other problems are still waiting for solutions. The use of model ice is developing rapidly.

Some suggestions of how to analyze such ice are made.

Breakthrough-loads on ice sheets diminish with duration of loading, but no satisfactory solution is available based upon classical procedures of applied mechanica.

The discovery of offshore oil in ice-infested waters has caused major concern to the design engineers.

Some of the problems associated with offshore structures are ice forces, ichag, and pile-up. Laboratory facilities have and will continue to solve many of the ice problems have been solved primarily due to laboratory studies. Also, the results of ice forces due to ice uptift have been virtually eliminated by controlled studies. Laboratories are becoming larger and more sophisticated.

This should result in an increase in laboratory studies and a decrease in field studies. Solutions will come faster because conditions can be precisely controlled.

SHOCK WAVES, SNOW DENSITY, LOADS (FORCES), SNOW STRENGTH, SHEAR STRESS, SNOW COMPRESSION, ANALYSIS (MATH-EMATICS).

EMATICS).

A dynamic constitutive law is used to study the response of medium-density snow to shock waves. The results show good correlation between theory and experiment, except for low-intensity shocks which produce small permanent density changes. In this case the validity of the data is questioned, although further experimental work is needed to settle this question. The results of this work also partially explain why snow is so effective in absorbing energy associated with stress waves. " is is felt to be due to the work-hardening characteristics of snow.

MP 1307 APPLICATION OF RECENT RESULTS IN FUNCTIONAL ANALYSIS TO THE PROBLEM OF WETTING FRONTS.

Nakano, Y., Water resources research, Apr. 1980, 16(2), p.314-318, 16 refs. 34-3948

YSIS (MATHEMATICS).

Traditionally, in hydrology and soil physics, wetting fronts appearing in porous media described by Darcy's law have not generally been considered to be singular surfaces. Some recent results from functional analysis are presented as evidence supporting the viewpoint that wetting fronts with a finite propagating speed generally are singular surfaces.

Gow, A.J., Glaciological data, May 1980, GD-8, p.91-102, 18 refs.

ICE CORES, DRILL CORE ANALYSIS, ANTARC-TICA—BYRD STATION.

TICA—BYRD STATION.

Both the Greenland and Antarctic ice sheets have been successfully core-drilled to bedrock, 1390 m at Camp Century, Greenland in 1966 and 2164 m at Byrd Station, Antarctica in 1968. Core and borehole studies at both sites have revealed a wealth of interesting results, especially at Byrd Station where extensive studies of cores were begun as soon as they were pulled out of the drill hole. Continuing investigations of these Byrd Station drill cores, including recent observations of apparent widespread recrystallization in certain sections of ice core, further confirm the importance

of initiating as many studies as possible at the drill site. Any list of the studies that should be conducted on deep ice cores must recognize two kinds of research: 1) those studies of a time-priority nature that must be initiated as soon as cores are pulled to the surface and, 2) other essential studies in which relaxation of the ice is not a factor. These latter studies can generally be deferred until cores are transported to more permanent storage facilities outside Antarctica. (Auth. mod.)

SMALL-SCALE TESTING OF SOILS FOR FROST ACTION.

34-3990

FROST ACTION, FROST HEAVE, ICE NEEDLES, SOIL WATER MIGRATION, SOIL TESTS.

SOIL WATER MIGRATION, SOIL TESTS.

A method is described for convenient study of frost action, including soil heaving and needle ice formation. The apparatus is simple and small and the procedure requires only 25 cu cm soil specimens. The method could be useful for screening either large numbers or limited quantities of soils or soil additives for frost susceptibility. The method described was used to perform a limited number of tests with several soils. The tests obtained action in the form of soil heave, ice heave, or ice needles, yielding maximum for soil heaves and 3 to 7 or more mm/h for ice heaves and ice needles. Initial trials showed that thickener additives and possibly other treatments can restrict frost action.

MP 1310 FATE AND EFFECTS OF CRUDE OIL SPILLED ON SUBARCTIC PERMAFROST TERRAIN IN INTERIOR ALASKA.

17 refs.

35-103 MELTWATER, HEAT TRANSFER, CONVECTION, ICE WATER INTERFACE, WATER TEMPERATURE EFFECTS, ICE MELTING, ANALYSIS (MATHEMATICS).

PERATURE, TEMPERATURE EFFECTS, ICE MBLITING, ANALYSIS (MATHEMATICS). An experimental study was conducted on the formation of a water layer containing a maximum density, its effect on the onset of convection, and the heat transfer characteristics of such a system. This water layer was formed by one odimensional melting (either from below or above) of a cylinder of bubble-free ice. The layer depth at the onset of convection was determined by locating the inflection point on the water layer depth versus time curve, and was compared with layer depth calculated from a linear stability analysis of an identical problem. The results were compared with the analytical work of Veronia and were found to be in excellent agreement. Formation of a constant temperature layer was observed by measuring the water temperature layer was observed by measuring the water temperature was found to depend on T(h) (warm plate temperature) for melting from below, but had a weaker dependence for melting from above. The heat flux to the melting surface increased inhearly with T(h) for melting from below, but had a weaker dependence for melting from above. Non-dimensional mean temperature profiles of the water layer were found to be in good agreement with those by Adrian for melting from above. In the case of melting from below, he mean temperature profile also fell into a single line with a somewhat higher value in the convection layer.

SNOW STUDIES ASSOCIATED WITH THE SIDEWAYS MOVE OF DYE-3.

ICE SHEET INTERNAL RADIO-ECHO RE-FLECTIONS AND ASSOCIATED PHYSICAL PROPERTY CHANGES WITH DEPTH.

Ackley, S.F., et al, Journal of geophysical research, Sep. 10, 1979, 84(B10), p.5675-5680, 13 refs. Keliher, T.E. 34-999

ICE SHEETS, ICE CORES, RADIO ECHO SOUNDINGS, ICE PHYSICS, ANTARCTICA— FOLGER, CAPE.

In this paper, the measured physical properties of core to bedrock taken at Cape Polger, East Antarctica, are used to compute a depth-reflection coefficient profile for comparison with the observed radio-echo reflections. The measurements available on physical properties are density variations, bubble size and shape changes, and crystal fabric variations. In calculations to differentiate the effects of the physical properties, it appears that density variations account for the primary contributions to the calculated dielectric property changes corresponding to the highest observed reflection coefficients. However, bubble changes alone can also account for reasonable, though lower, reflection coefficients at the depths corresponding to the properties of the depths corresponding to the property changes. with the observed radio-echo reflections The me

though lower, reflection coefficients at the depths corresponding to observed reflections. Crystal fabric variations correspond poorly with the reflection locations. The close correspondence between the depths of the bubble shape changes (which are definitely deformational features) and the depths of the density variations, and between both of these and the radio-cohe layers, indicates that deformational events in the ice sheet's history are represented by the variations in physical properties and associated radio-echo records. REVIEW OF BUCKLING ANALYSES OF ICE SHEETS.

Sodhi, D.S., et al, U.S. Army Cold Regions Research and Engineering Laboratory, June 1980, SR 80-26, p.131-146, ADA-089 674, 14 refs.
Nevel, D.E.

ICE SHEETS, ICE LOADS, ICE PRESSURE, ICE STRENGTH, ANALYSIS (MATHEMATICS),

PLATES.

A review of the buckling analyses of floating ice sheets is presented. The theory used is that of a beam or plate on an elastic foundation. For beams, the results for all possible boundary conditions are presented and discussed. For plates, results of numerical solutions for a semi-infinite plate loaded over part of its boundary are presented and discussed. One solution is presented for an infinite plate loaded radially at a hole in the plate. In addition, results for wedge-shaped beams and plates are presented and discussed. Wedge-shaped ice sheets frequently occur due to previous cracking in the ice.

SEA ICE, FAST ICE, POLARIZATION (WAVES), ANISOTROPY, ICE OPTICS, ICE COVER THICK-NESS, ELECTROMAGNETIC PROPERTIES.

NESS, ELECTROMAGNETIC PROPERTIES.
The frequency dependence of the polarization-rotation properties of fast ice upon radiowaves in the HF-VHF range were studied at Pt. Barrow, Alaska, in the early spring of 1979. Five sites were investigated at frequencies between 10 and 173 MHz and at each site cores were taken and then physical properties measured. The polarization was studied with a pair of crossed dipole antennas, one a transmitter, the other a receiver, both of which were rotated simultaneously as a fixed unit. This procedure was designed to produce a four-lobe cloverleaf pattern with maximum coupling occurring when the antennas were aligned at 45 deg to the c-axis direction. The results showed strongest polarization between about 35 and 65 MHz. Above this band the high de conductivity of the sea ice which was measured accounts for the lack of cross coupling, but it is not yet understood why the data was so erratic below this band. Reperimental difficulties are also discussed.

(WAVES), MATHEMATICAL MODELS.

The contribution of brine layers to observed reflective anisotropy of sea ice as 100 MHz is quantitatively assessed. The sea ice is considered to be a stratified, inhomogeneous, anisotropic dielectric consisting of pure ice containing ordered arrays of conducting inclusions (brine layers). Below the transition zone, the ice is assumed to have constant azimuthal caxis orientation within the horizontal plane, so the orientation of brine layers is uniform. The brine layers are also assumed to become increasingly well-defined with depth since adjacent brine inclusions tend to thus together with increasing temperature. A theoretical explanation for observed reflective anisotropy is proposed in terms of anisotropic electric flux penetration into brine layers. Penetration anisotropy and brine layer geometry are linked to anisotropy in the complex dielectric constant of sea ice. Subsequently, a numerical method of approximating the reflected power of a plane wave pulse incident on a slab of sea ice is presented and used to show the contribution of the above effects to the observed reflective anisotropy.

33-693 ICE REMOVAL, BUBBLING, ICE MELTING, HEAT TRANSFER, ICE COVER THICKNESS, AIR TEMPERATURE, WATER TEMPERATURE, MATHEMATICAL MODELS.

An analysis of a point source bubbler system used to induce local melting of an ice cover is presented. The analysis uses empirical results of bubbler plume experiments and impringement heat transfer results to determine the rate of melting at the underside of an ice cover. Through a simple energy budget analysis of the ice cover, the melting of the ice cover and resulting extent of open water are determined as a function of air temperatures, depth and

air discharge of the source, and water temperature.

analysis leads to a numerical simulation and an exan
simulation is presented.

LOW TEMPERATURE TESTS.

Prior work has revealed the existence of one or more low temperature phase changes in clay water systems in the temperature range -20C to about -50C. The number and the temperatures at which these phase changes appear seems to be associated with the type of exchangable ion(s) and the number and nature of individual water domains present. In this paper, we report the results of low temperature differential calorimetry on monimorillonite and nontronite clays at high water and high salt contents. The presence of electrolytes at high concentration is shown to have a very marked effect. The low temperature phase changes are completely absent at high electrolyte concentrations in these clay water systems. The presence of electrolytes also was observed to have a distinctive effect on the shape of the initial freezing peak associated with ice segregation.

TY, ANALYSIS (MATHEMATICS).

The mixing theory of Polder and Van Santen is revised for application to three cases of wet snow. The dielectric constant is calculated for a range of liquid contents and porosities. These calculated values compare favorably with experimental data for the two cases in which data are available. The application to a snow cover with a heterogeneous distribution of liquid is discussed. The possibility of applying this theory to calculate the imaginary part of the dielectric constant must be explored further.

ridier, w.D., iii. 35-2168 SEA ICE, DRIFT, ICE WATER INTERFACE, BOUNDARY LAYER, MATHEMATICAL MOD-ELS, VISCOUS FLOW.

ELS, VISCOUS FLOW.

The finite-element formulation of a linear viscous sea ice model has been presented. The temporal ice acceleration term is included in the momentum equations in order to compute monsteady ice drift rates. This model is applied to the Strait of Belle lale, where strong tidal streams move the pack ice back and forth. Using idealized sinusoidal variations of the tidal streams, it is found that the time lag between the water and the ice velocities is dependent upon the viscosity parameters. These results indicate that the ice is not drifting freely and the boundary layer near the above affects the ice movement in the Strait. The viscosity parameters used in this study are small in order to simulate a reasonable time lag between the ice and water velocities. The high shearing near the above necessitates low viscosities for proper simulation of the flow of pack ice in the Strait. ice in the Strait.

ICEBERG WATER: AN ASSESSMENT. Weeks, W.F., Annals of glaciology, 1980, Vol.1, p.5-10. 27 refs.

ICEBERGS, WATER SUPPLY, ICEBERG TOW-ING.

ING.

This review of the idea of using icebergs as a source of fresh water starts with a historical survey covering the period up to April 1980 and stresses how the approach to the subject has changed with time. Both the progress that have either just surfaced or never been adequately addressed are discussed. It is concluded that successful tows to Australia, clearly the most easily-reached potential delivery site, are possible if icebergs can retain their structural integrity during tows in high seas and if schenes can be developed for docking and processing. Tows to sites in the northern hemisphere such as Saudi Arabia and California are significantly more difficult and will remain so until an effective and operationally-realistic method is developed for isolating the iceberg from the warm sea-water that will be encountered during part of the tow. Whatever the ultimate resolution of the iceberg water proposal may be, research stimulated by this idea has already resulted in a major improvement in our knowledge of the life and time of real icebergs in real oceans. MP 1366 ACOUSTIC EMISSION RESPONSE OF SNOW. St. Lawrence, W.F., Journal of glacology, 1980, 26(94), p.209-216, 10 refs., In English with French and German summaries.

SNOW ACOUSTICS, AVALANCHE TRIGGER-ING, AVALANCHE FORMATION, STRESS STRAIN DIAGRAMS, RHEOLOGY, ULTRA-SONIC TESTS, MATHEMATICAL MODELS.

In this work a model of the ultrasonic acoustic emission response in snow is developed. The model derived considers the acoustic emission response in snow as a function of stress and strain. It is suggested that the acoustic emission activity in snow is a quantitative indication of the creep ruprure taking place in the material. The governing different

tial equation is developed; an example is then present that considers the applicability of this equation to the releas of certain types of avalanche.

LANDSCAPES.
The propagation of pressure waves in low-density snow is investigated analytically to determine the variation of wave pressure and wave speed with density and frequency. The results abow that, for pressure waves that produce finite volumetric deformations, both pressure jump across the wave and wave-speed increase with initial density and final density. The pressure jump was also found to increase with twave frequency if other parameters were held constant, although the dependence on frequency is not as strong as the dependence on the initial and final densities. The relationship between pressure jump and frequency implies that high-frequency waves would tend to dissipate more quickly than lower-frequency waves, although like pressure, the attenuation rate would not be strongly frequency dependent.

MP 1368
THERMODYNAMICS OF SNOW METAMOR-PHISM DUE TO VARIATIONS IN CURVA-

Ito), when the base of imposed temperature gradients, the metamorphism of dry snow is dominated by the alow process of vapor diffusion between surfaces of different radii of curvature. remain or any season is commission by the slow process of open different radii of curvature. This process is so slow in a seasonal snow cover (where temperatures normally change on the scale of hours or days) that vapor migration is usually dominated by the imposed temperature gradient. Thus radius of curvature contributes to but does not control metamorphism except for short periods in very fresh snow. As opposed to dry anow, liquid-esturated anow (i.e. pore space filled by the melt) is metamorphosed by heat flow arising from relatively large temperature differences among the particles. Grain growth in liquid-esturated snow is rapid because of the large temperature differences at nearly constant liquid pressure. In wet snow with low liquid content (2-5% by volume), grain growth is much slower than under conditions of liquid saturation.

SNOW DEFORMATION, SNOW COVER STRUC TURE, STRESS STRAIN DIAGRAMS, SNOW COMPRESSION, VELOCITY, SNOW ACOUSTICS, ANALYSIS (MATHEMATICS).

TICS, ANALYSIS (MATHEMATICS). In this paper a constitutive equation which describes the miazial deformation of snow is developed. The basic assumption underlying this work is that the streat-atrain response can be derived by considering the structure of the material. The equation which describes the plastic portion of the deformation is developed by considering the relationship between three fundamental variables: the mean specing between ice grains, the relatative velocity between rains, sad the fraction of the total number of grains which participate in the deformation process. The mean distance between ice grains is determined by a stereological investigation of the snow structure, and the velocity component is found by empirically characterizing the relatation of the snow. To determine the mobility of the ice grains acoustic emissions for constant rates of deformation is derived and applied to a number of tests. Combining the above variables produces a compressive and tensile constitutive

equation which reflects the behavior of the snow under both uniaxial deformations.

CYCLIC LOADING AND FATIGUE IN ICE. Mellor, M., et al, Cold regions science and technology, Jan. 1981, 4(1), p.41-53, 4 refs. Cole, D.M.

35-2417

ICE CRYSTALS, DYNAMIC LOADS, ICE STRENGTH, STRESS STRAIN DIAGRAMS, FATIGUE (MATERIALS), ICE CREEP, TIME

FACTOR.

Isotropic polycrystalline ice was subjected to cyclic loading in uniaxial compression at -5C, with stress limits 0-2 and 0-3 MPa, and frequencies in the range 0.043 to 0.5 Hz. Stress-strain eccords showed hysteresis loops progressing along the strain axis at non-uniform rates. The effective secant modulus, which was about half the true Young's modulus, decreased during the course of a test. The elastic strain amplitude and the energy dissipated during a loading cycle both increased with increase of time and plastic strain. Strain-time records gave mean curves which were identical in form to classical constant stress creep curves, with a small cyclic alternation of recoverable strain about the mean curve. The results of the tests suggest that maximum resistance under compressive cyclic loading occurs at an axial plastic strain for ductile yielding under constant same as the failure strain for ductile yielding under constant stress and under constant strain-rate.

31-448 SEA ICE, ICE COVER EFFECT, CLIMATE, SPACEBORNE PHOTOGRAPHY, PHOTOIN-TERPRETATION, HEAT LOSS, MICROWAVES. SPACEBORNE PHOLOGRAPHY, PHOTOINTERPRETATION, HEAT LOSS, MICROWAVES.
Ice extent charts prepared from satellite images by the U.S.
Naval Fleet Weather Facility and passive microwave emission
data from the Nimbus V satellite were examined for the
winters of 1973 and 1974 to determine the variation between
the two years of the heat loss by the atmosphere because
of variations in sea ice extent and concentration. The
microwave data indicate that most of the area within the
ice edge is less than 80% ice covered even during the
coldest part of the year, probably because of ocean currents,
waves, and swell, and convergence and divergence in the
atmospheric forcing fields. Since the winter heat and
moisture transports from open water are about two orders
of magnitude larger than from an equal area of sea ice,
even small areas of open water within the ice edge can
greatly affect the energy exchange. These new data are
compared with the assumption of 100% ice cover within
the ice edge and with previously assumed mean values for
the total area covered by ice in calculating the heat lost
by the atmosphere during the winter period in high southern
latitudes. A rapid decrease in sea ice extent observed
during the winter of 1973 is correlated with a nearly realtime adjustment by the atmosphere to the change in the
heat loss caused by the removal of the ice. This example
indicates that sea ice dynamics is influential not only in
long-term climate, but in synoptic-scale weather patterns
as well.

31-450 SEA ICE, ICE CRACKS, ISOSTASY, ICE PHY-SICS, ICE DENSITY.

In the AIDJEX ice pack model the formation mechanisms for ice cracks are ignored because of the many processes by which cracks may form. The authors question this concept and particularly the mechanism of isostatic imbalance. They cite the Young's modulus used in the AIDJEX model as being not representative of sea ice and that beam experiments in static tests lead them to question the validity of a purely elastic analysis.

ICE SHEETS, ICE CRYSTAL STRUCTURE, RHEOLOGY, ICE DEFORMATION, ANTARCTICA—BYRD STATION.

Crystalline textures and fabrics of ice cores from the 2,164-m-thick ice sheet at Byrd Station, reveal the existence of an anisotropic ice sheet. A gradual but persistent increase in the c-axis preferred orientation of the ice crystals was an anisotropic ice sheet. A gradual but persistent increase in the c-axis preferred orientation of the ice crystals as observed between the surface and a depth of 1,200 m. This progressive growth of an oriented crystal fabric is accompanied by a twentyfold increase in crystal size between 56 and 500 m, followed by virtually no change in crystal size between 600 and 1,200 m depth. A broad vertical clustering of c axes develops by 1,200 m. Between 1,200 and 1,300 m, the structure transforms into a fine-grained messaic of crystals with their basal gide planes now oriented substantially within the horizontal. This highly oriented fine-grained structure, which persists to 1,800 m depth, is compatible only with a strong horizontal shear deformation in this part of the ice sheet. Rapid transformation from single- to multiple-maximum fabrics occurs below 1,800 m. This transformation, accompanied also by the growth of very large crystals, is attributed to the overriding effect of relatively high temperatures in the bottom layers of old cet Byrd Station rather than to a significant decrease in stress. The zone of single-maximum fabrics between 1,200 and 1,800 m also contains numerous layers of volcanic dust which appear to be actively associated with shearing in the ice sheet. Some slipping of ice along the botton structures and fabrics of the ice indicate that plastic deformation (intracrystalline gide) in the zone of strong single-maximum fabrics and movement of ice along discrete shear planes situated well above bed rock are also major contributors to the flow of the ice sheet. (Auth. mod.)

The consequences of off-road activities depend on when the activity occurs (summer vs. winter), the degree of impact, the nature and response of the underlying permafrost to the surface modification, and the rate at which the damaged environment will recover. Regulations based on a knowledge of the environmental variables and how they reset to impact are required to minimize impact in these areas which are sensitive to human and natural perturbations. We should not underestimate the requirement for good environmental information and adequate resource mapping as first, necessary

VEHICLE FOR THE FUTURE.

VEHICLE FOR THE FOLURE.

AIR CUSHION VEHICLES, ARCTIC LAND-SCAPES, DAMAGE, ENVIRONMENTAL IM-PACT, GROUND THAWING.

PACT, GROUND THAWING.

The U.S. Army Cold Regions Research and Engineering Laboratory (USACRREL) has evaluated effects of sir-cushion nehicles (ACV's) on surfaces on Alsaka's Arctic Stope. Most ACV surface impact was from sbrasion by the vehicle skirts rather than air flow, which merely removed loose litter. Vehicle speed and surface micro-relief both affected surface damage. The ACV damaged the surface less than other vehicles tested and caused less accelerated soil thaw; trails over which the ACV passed recovered faster. Size, payload, cost, terrain characteristics, and availability are among the conditions that determine the kind of vehicle needed for particular job. No single vehicle, now or in the future, can fill all the necessary and desirable requirements and cause little surface damage. Other aspects of off-road travel, such as route selection, trail improvement and protection, operator sensitivity, and access priorities also affect surface damage. More important than vehicle design and selection are the management decisions to be made concerning regulation of off-road travel.

SUBJECTION MICROSCOPY, CRYOGENIC SOILS, MORAINES, SOIL COMPOSITION, GRAIN SIZE, WEATHERING, ANTARCTICA—VICTORIA LAND.

The textures of morainic soils from southern Victoria Land were investigated, using a scanning electron microscope fitted with an energy dispersive X-ray analyzer. Electron micrographs of soil grains from lower Wright Valley showed sharp edges and smooth surfaces, indicating a low degree of mechanical and chemical weathering. The soil grains were 11% quartz and 4% magnetite. Chlorides were found on 7% cal and chemical weathering. The soil grains were 11% of the soil grains. By contrast, electron micrographs of soil grains from the Beacon Valley showed rounded grains indicating a high degree of mechanical and chemical weathering. The soil grains were 20% quartz. Rhombobedral crystals CaSO4 were found on 60% of the soil grains. Chlorides were found on 30% of the soil grains. Because of the high degree of weathering, it was concluded that the morainic soils from the Beacon Valley are much older than those of the lower Wright Valley.

WINDOWS, COLD WEATHER CONSTRUC-TION, WEATHERPROOFING, MOISTURE, CLI-MATIC FACTORS, COUNTERMEASURES.

MATIC FACTORS, COUNTERMEASURES.

Extreme cold causes heavy buildup of frost, ice and condensation on many windows. It also increases the incentive for improving the sirtightness of windows in Alaska to avoid moisture accumulation in homes and barnacis. We base our conclusions on a two-year study of Alaskan military bases that included recording humidity and temperature data, observing moisture accumulation on windows and measuring airtightness with a fan pressurization device. Our study shows that tightening Alaskan windows to permit only 30% of the air leakage allowed to current American standards for window airtightness is economically attractive.

WASTE TREATMENT, WATER TREATMENT, PLANTS (BOTANY).

PLANTS (BOTANY).

Aquaculture systems for wastewater treatment often include plants, finned fish, animals and microorganisms in various combinations in aquatic settings such as ponds, marshes, bogs and other forms of wetlands. Natural settings have often been used in the past but there is a trend toward constructed systems which permit more reliable management at higher rates of treatment. This paper evaluates the potential for application of aquaculture concepts for wastewater treatment in cold climates. Constructed wetlands and the enclosed high rate processes offer the most promise of the concepts considered. Systems based on plants are more efficient, require less area and are easier to control than concepts involving higher forms of animals.

AIR POLLUTION, CHEMICAL ANALYSIS, EN-VIRONMENTAL IMPACT, MOTOR VEHICLES, HUMAN FACTORS, STANDARDS.

Air quality measurements were made for both gases and particulates at several locations near Pairbanks, Alaaka, during winter. The results indicated that carbon monoxide levels downtown frequently exceeded air quality standards and were significantly elevated at more rural locations up to 22 km from the downtown area. High levels were found to be associated with temperature inversions. Nitric oxide levels were measured and found to range from less than 50 to over 500 parts per billion (ppb) downtown. Levels of 1 to 68 ppb were measured in a more rural location. The major source of both CO and NO at Fairbanks was found to be auto exhaust. Levels of particulate lead in the downtown area were found to exceed Federal Standard for all 4 winter months. Lead levels at the more rural site were only about one-tenth those of downtown and did not exceed standards. not exceed standards

THICKNESS, RADAR ECHOES.

The Alaskan Projects Office of Cold Regions Research and Engineering Laboratory has been studying the forces imposed on the Yukon River bridge by ice during breakup. The study involved four consecutive breakups from 1977 thru 1980. Forces have been measured using load cells mounted on the front of the number 5 pier to intercept the ice is it strikes the pier. Accelerometers mounted on piern number 4 and 5 were used to measure the response of the pier to the ice impacts. Calibration procedures were employed to determine a transfer function which relates the accelerations to the applied forces. Ice thicknesses were measured using short pulse radar techniques. River ice damaged or destroyed the first generation load cell designs, but some useful dats was obtained before failure. Radar techniques show some promise for the measurement of ice techniques show some promise for the measurement of ice thicknesses during breakup.

The techniques for analyzing velocity profiles should be carefully considered in shallow streams where the flow depth is less than 1 m. The two procedures, a) mean and maximum velocity determinations and b) intercept evaluation of log (depth)-velocity plots, yield different results for the various resistance coefficients and shear stress values. The mean-max-velocity method generally predicts higher values than the other and is recommended for shallow streams. The minimum distance from a boundary to the position of maximum velocity for a good velocity profile appears to be roughly 15 to 20 cm with a 5 cm diameter sensor.

MARS (PLANET), SOIL WATER, ADSORPTION, WATER VAPOR, THERMODYNAMICS, SOIL MICROBIOLOGY, TEMPERATURE EFFECTS.

MICROBIOLOGY, TEMPERATURE EFFECTS.
One of the scientific objectives of the Viking Mission to Mars was to accomptish an analysis of water in the Martian regolith. The analytical scheme originally suvisioned was severely compromised in the latter stages of the Lander instrument package design. The presence of a duricrust at one of the Lander sites is taken as possible evidence for the presence of hygroscopic minerals on Mars. The demonstrated presence of atmospheric water vapor and thermodynamic calculations lead to the belief that adsorbed water could provide a relatively favorable environment for endolithic organisms on Mars similar to types recently discovered in the dry antarctic deserts.

MP 1410 ESTIMATION OF HEAT AND MASS FLUXES OVER ARCTIC LEADS.

POLYNYAS, SEA ICE, HEAT TRANSFER, MASS TRANSFER, TURBULENT EXCHANGE, HEAT FLUX, ANALYSIS (MATHEMATICS).

PLUX, ANALYSIS (MATHEMATICS).

Recent work on the turbulent transfer of scalar quantities following a step increase in the surface value of the scalar is directly applicable to the problem of estimating heat and mass transfer from Arctic leads in winter. With the transfer relations, turbulent fluxes can be computed from standard meteorological observables; and from the Nusselt number equality, partitioning of the turbulent fluxes can be evaluated—in particular, the partitioning of the heat flux between sensible and latent components.

PERMAPROST BENEATH RIVERS, PILE DRIV-ING, FOUNDATIONS, BRIDGES, PERMA-FROST PRESERVATION, BEARING STRENGTH, SETTLEMENT (STRUCTURAL), SOIL TEMPERATURE, DESIGN CRITERIA, FROST HEAVE, COUNTERMEASURES, STREAMS.

This cooperative research study has focused considerable attention on the ground temperatures existing beneath and adjacent to streams in permafrost areas. An appreciation of the changes in the thaw area beneath the stream, both at the time of construction and for the life of the structure, is essential to proper siting of the bridge foundation. Location of abutments and piers outside of the potential thaw zone of the stream, or penetration at the most advantageous

points to depths sufficient to achieve the required bearing capacity, is essential. The design of piles based on depth of embedment, affreeze strength or dynamic driving formulas in frozen soils is of little value if the permafrost condition is later destroyed. Emphasis must be placed on retaining the original permafrost conditions and providing for frost

DRILL CORE ANALYSIS.

Prior work resulted in the development of techniques to measure the unfrozen water contents in frozen soils by nuclear magnetic resonance (NMR). It has been demonstrated that NMR is a promising new method for the determination of phase composition (the measurement of unfrozen water content as a function of temperature) which circumvents many of the limitations inherent in the adiabatic and isothermal calorimetric techniques. The NMR technique makes it possible, in a non-destructive, non-intrusive way, to explore hysteresis by determining both cooling and warming curves. Corrections are made for dissolved paramagnetic impurities which have the effect of increasing the signal intensity at decreasing temperatures. The results demonstrate that NMR techniques can be effectively utilized both at and below the melting point of ice in frozen soils and that accurate melting points (freezing point depressions) can be determined.

THEALT SIS, LESIGN.

Treatment ponds are a cost-effective alternative for municipal wastewaser treatment. When compared to other secondary treatment alternatives, ponds are generally the least costly, require less energy and less skilled operational attention. They can be designed to consistently meet BOD removal requirements and can achieve significant reductions in nutrients, bacteria, and viruses.

YSIS (MATHEMATICS).

A traveling wave solution was derived for the problem of simultaneous flow of water and sir through homogeneous porous media.

The properties of the solution generally depend upon the hydraulic characteristics of a given problem. The properties of the solution are presented for a specific case in which the hydraulic characteristics are given in specific functional forms. For this specific case a singularity occurs in the solution of both a saturated-unsaturated boundary and a wetting front. Some applications of the solution are discussed.

A 2-year field study was performed to determine the seasonal growth and nutrient accumulation of a forage grass receiving 7.5 cm/week of domestic primary-reside waste water. The average N and P concentrations in the waste water were 31.5 and 6.1 mg/liter, respectively. An established sward of Pennlate' orchardgrass (Dectylis glomerate L.) was managed on an annual three-cutting system. Grass samples were taken periodically during the growing season to determine plant dry matter accumulation and uptake of N, P, and K.

SRA ICE DISTRIBUTION WEATHER WIND

SEA ICE DISTRIBUTION, WEATHER, WIND (METEOROLOGY), OCEAN CURRENTS, AN-

TARCTICA.
Within the last decade data on sea ice from satellite coverage have become available for the Southern Hemisphere. The data record is reviewed with some consideration given to the different mechanisms of ice advection by wind forcing, thermodynamic growth, and ocean mixing. These mechanisms control the ice edge around Antarctica and lead to the characteristic advance-retreat relationships for the Weddell Sea, East Antarctica, and the Ross Sea. Recent statistical and function (BOF) analyses have shown two primary areas of higher annual variation of sea ice conditions which are presumed to be of dynamic (winds and currents) rather than thermodynamic (temperature) origin. It is postulated that atmospheric forcing of the sea ice system causes changes in sir-sea energy transfers that then drive the atmospheric to its own anomaly condition. Further correlations that may define the mechanism of sea ice response to the forcing fields and supply stronger evidence of weather and climate responses to ice variations, may be available by analysis of the Global Weather Experiment drifting buoy data obtained during 1979. (Auth. mod.) (Auth. mod.)

SEA-ICE ATMOSPHERE INTERACTIONS IN THE WEDDELL SEA USING DRIFTING BUOYS.

SEAICE, ATMOSPHERIC CIRCULATION, PACK ICE, ATMOSPHERIC PRESSURE, DRIFT, AIR TEMP ATURE, WIND FACTORS, WEDDELL

SEA.

Air-dropted data buoys were placed on the Weddell Sea pack icc during December 1978. These buoys transmit information via the NIMBUS satellite giving data on their position, surface pressure, and surface temperature. The velocities of four buoys during fall showed values up to 40 cm/s (35 km/day). The highest sustained velocities appear to coincide with sudden drops in air temperature. Schwerdtfeger (1979) has postulated a model of winds in the western Weddell Sea dominated by thermal rather than pressure gradient forces due to the damming of cold air from continental barrier and katabatic winds against the mountains of the Antarctic Peninsula. This model is examined to explain the drift rates associated with cold air outbreaks. (Auth.) (Auth.)

NAVIGATION.

A 19-year record of annual closing and opening dates of the Lake Champlain ferry season was found to accurately approximate the freeze-over and breakup dates for the ferry crossing area between Gordon Landing, Vermont, and Cumberland Head, N.Y. These lake navigation records, when compared statistically with the lake's wintertime thermal structure and climatological data for the same years of at nearby Lake Champlain locations, allowed accurate predictions of ice formation. From nearby air temperature records, cumulative freezing degree-day (C) curves were pictited for each year of record and ice formation dates and standard deviations were predicted with considerable accuracy. Several methods of predicting ice formation on Lake Champlain were attempted. The most accurate approach used a combination of water temperatures and freezing degree-days. A method of predicting ice growth rates is shown and the influence of wind speed on ice cover formation and prediction on a large body of water such as this is also discussed. MP 1430 MP 1430

SEA ICE, DRIFT, BIOMASS, WEDDELL SEA. The purpose of this study was to investigate several characteristics of Weddell Sea pack ice that may affect the relative roles of dynamics and thermodynamics of pack ice development in this region. The physical and structural properties of the pack ice were surveyed using core samples. Significant amounts of frazil ice were found. If this formation of frazil ice is as widespread as suspected, then the role of deformation (the opening and closing of leads and polynyas) may have a greater role in the formation of Weddell Sea pack ice than similar processes do in the arctic pack. Four data buoys were deployed. The initial locations are shown, and the studies for which the buoy data will be used are discussed. Observations during the cruise confirmed the ubiquitous presence of algae in nearly all forms of ice sampled and point to close links between pack ice formation and enhanced algal production. ed algal production.

A procedure is described for monitoring the microfracturing of ice plates subjected to constant loads. Sample time records of fresh water ice plate deflections as well as corresponding total acoustic emission activities are presented. The linear elastic as well as viscoelastic response for a simply supported rectangular ice plate is given. In the present investigation acoustic emission methods are used to study the microfracturing activity in polycrystalline ice subjected to flexural loads. The relationship between acoustic emissions and the time dependent inelastic flexural deformation in ice is studied. Furthermore, the influence of the magnitude of the applied load and the rate of deformation on cracking activity is explored. cracking activity is explored.

SOME APPROACHES TO MODELING PHASE CHANGE IN FREEZING SOILS.

35-3670
SOIL FREEZING, PHASE TRANSFORMATIONS, THERMAL REGIME, UNFROZEN WATER CONTENT, SOIL WATER, MATHEMATICAL MODELS.

Phase change effects associated with freezing soils dominate the thermal state of the soil regime. Furthermore, freezing

of soil water influences the soil moisture regime by providing a moisture sink which tends to draw mobile soil moisture to freezing fronts. Consequently, it is critical to general purpose models that soil water phase change effects and the interrelated problem of estimating the moisture sink effects (i.e., conversion of liquid water to ice) be accurately modeled. The choice of such a model will not only influence the precision of simulated temperatures and water contents in a freezing soil, but will also have a significant impact on computational efficiency. A review of several current models that assume unfrozen water content is functionally related to subfreezing temperatures indicates that within a freezing soil the soil water flow model and heat transport model parameters are restricted in spatial gradients according to the spatial gradient of modeled unfroze water content. A freezing soil model based on the concept of isothermal phase change of soil water is proposed as an alternative approach.

MP 1438 CYLINDRICAL PHASE CHANGE APPROXIMA WITH EFFECTIVE THERMAL DIF-

TION WILL FUSIVITY.

FUSIVITY.

Lunardini, V.J., Cold regions science and technology, Apr. 1981, 4(2), p.147-154, 13 refs.

PHASE TRANSFORMATIONS, FREEZE THAW CYCLES, THERMAL DIFFUSION, PERMA-FROST HEAT BALANCE, LATENT HEAT, PIPES (TUBES), ANALYSIS (MATHEMATICS).

(10BBS), ANALYSIS (MATHEMATICS).

No exact, general, solution exists for phase change in a cylindrical geometry. In fact, even approximate solutions are rare and limited in applicability. The use of the effective thermal diffusivity concept has allowed a closed form approximate solution to be generated for phase change around a circular cylinder in an indefinite medium. The effective diffusivity method permits solutions to be found for phase change problems merely by solving the usually linear, zero latent heat problem analogous to the phase change problem. Phase change problems are often intractable with the usual mathematical methods. The cylindrical formulae siven here are abourt to be of accordable accuracy. with the usual mathematical methods. The cylindrical formulae given here are shown to be of acceptable accuracy, for most engineering purposes, over a wide range of parameters. No other simple, closed form, approximation is known for the cylindrical system. Although the accuracy of the effective diffusivity method has been demonstrated for the cylindrical geometry, application to other geometries must be verified.

COASTAL-INLAND DISTRIBUTIONS OF SUM-MER AIR TEMPERATURE AND PRECIPITAtion in northern alaska.

TUNDRA, PRECIPITATION (METEOROLOGY), AIR TEMPERATURE, SHORES, LONG RANGE FORECASTING, WIND FACTORS, UNITED STATES—ALASKA—NORTH SLOPE.

STATES—ALASKA—NORTH SLOPE.
Using data from summer air temperature stations from the inland tundra to the immediate coastal area, regression analyses of the air temperature data from 1975 to 1978 were used to predict temperature wates across the Alaskan Arctic Coastal Plain based upon latitude and longitude. This provides the best approximation of average values based on existing data. Mean monthly temperature, mean daily range of temperature, and thawing-degree days all increase with distance from the coast. The estimated July normal for Attasook, 48 km south of the coast, is 3.7 C, while the established 30-yr normal for Barrow, on the coast, is 3.7 C. The July average temperature 6 km due south of the open water of Prudhoe Bay is 2 C higher than on the immediate coast. Within the area under the dominant influence of the sea breeze, regression analyses suggest a more precise relationship between air temperature and distance along the prevailing wind vector (N75 E) than between temperature and distance due north to the sea.

MODELING NITROGEN TRANSPORT AND TRANSFORMATIONS IN SOILS: 1. THEORETICAL CONSIDERATIONS.

MATHEMATICAL MODELS.

A numerical model was developed to simulate water and nitrogen transport and transformations through water-unsaturated, multilayered soil profiles. The nitrogen transformation processes considered were nitrification, denitrification, immobilization, mineralization, and ionic exchange of ammonism. Plant uptakes of water and nitrogen were also included. An explicit-implicit finite difference approximation method was used to solve the nitrogen transport and transformation equations simultaneously with the water flow equation. Model evaluation and sensitivity analysis for a wide range of values for the rate of nitrification, distribution coefficient for ammonium exchange, and rate of N uptake were investigated. (Auth.) (Auth.)

SOIL CHEMISTRY, NUTRIENT CYCLE, TRANS-FORMATIONS, WASTE TREATMENT, WATER TREATMENT, IONS, MODELS.

TREATMENT, IONS, MODELS.
The nitrogen model described in Part 1 was evaluated using experimental data from a greenhouse lysimeter study for two soils, Windsor sandy loam and Charlton silt loam. Secondary treated waste water was applied to each soil at the rate of 3.8 centimeters twice weekly for 25 weeks. Purthermore, (15) N-enriched NH4 cation-N was applied, at the beginning of the experiment, in one waste water application. A mixture of grasses was grown on esch lysimeter and was harvested every 2 to 4 weeks. Solution samples were collected and analyzed for N, and the soil water pressure head was monitored frequently at different soil depths. Model predictions agreed well with pressure head data with depth and time, as well as gravimetrically determined soil water content with depth for the two soils. (Auth. mod.)

SOIL CHEMISTRY, WASTE DISPOSAL, WATER TREATMENT, IRRIGATION, WASTE TREAT-MENT.

MENT.

The concentrations of dissolved inorganic phosphate (DIF) in soil solution collected at 0.3 and 1.6 m in soils which had received municipal waste water for 4 and 13 years ranged from 7.3 to 13.9 microgram P/ml. In some cases, these concentrations were higher than that in the added waste water. Sorption studies indicated that the ability of soils from the control site to remove added P from solution was low. Waste water addition caused a substantial decrease in the P sorption capacity of surface soils and a marked change in isotherm. Sorption capacity generally increased down the profile to 60 cm on the treated sites. Only a small proportion of the total P accumulated from waste water addition was in the organic form. Large amounts of P were extractable by 0.01 M CaCl2, particularly in the upper 45 cm of the profiles receiving waste water. Although lack of crop removal of P and a high infiltration rate may be partly responsible for the poor performance of the Manteca system in terms of P removal from waste water, the very low P sorption capacity of the soil is regarded water, the very low P sorption capacity of the soil is regarded as the major factor.

ICE CONTROL AT NAVIGATION LOCKS. Hanamoto, B., Specialty Conference Water Forum '81, San Francisco, Aug. 10-14, 1981. Proceedings. Vol.2. New York, American Society of Civil Engineers, 1981, p.1088-1095.

35-4168 CONTROL, ICE NAVIGATION, LOCKS (WATERWAYS), BUBBLING, TESTS.

A method for controlling ice at navigation locks is presented. A high-flow air screen placed across the entrance of a lock holds back ice floating downstream or pushed head of traffic. The analysis is based on low-flow bubbler systems. The applicability of this analysis to high-flow systems is examined by conducting laboratory tests. (Auth.)

ICE CONTROL ARRANGEMENT FOR WINTER NAVIGATION.

Perham, R.E., Specialty Conference Water Forum '81, San Francisco, Aug. 10-14, 1981. Proceedings. Vol.2, New York, American Society of Civil Engineers, 1981, p.1096-1103, 9 refs.

ICE NAVIGATION, ICE CONTROL, RIVER ICE, ICE JAMS, ICE BOOMS, WATER LEVEL.

ICE JAMS, ICE BOOMS, WATER LEVEL.

This paper presents a four-year summary of the main effects of the booms on ice and ship interaction and vice-versa.
Throughout the four winter seasons, relatively small quantities of ice were lost over and between the booms. Ships usually slid through without influencing the boom force levels, although, at times, the changes they wrought could be large. One boom needed strengthening and artificial islands were added for ice stability upstream. These devices and frequent icebreaker operations were able to compensate for the ice movement caused by winter navigation in this area.

KINETIC NATURE OF THE LONG TERM STRENGTH OF FROZEN SOILS.

Plah, A.M., International Symposium on Ground Freezing, 2nd, Trondheim, Norway, June 24-26, 1980. Preprints, Trondheim, University, Norwegian Institute of Technology, 1980, p.95-108, 23 refs.

PROZEN GROUND STRENGTH, SOIL CREEP, STRESSES, SOIL TEXTURE, TRIAXIAL TESTS, RHEOLOGY, TEMPERATURE EFFECTS, ANALYSIS (MATHEMATICS).

ANALYSIS (MATHEMATICS).

Temperature dependencies of the failure activation energy of frozen soils in the temperature range from -0.55 to -20C were studied. The analysis was based upon experimental data on the long-term failure of six frozen soils: Manchester and Ottawa sands, Suffield and Bat-Bayoss clays, Hanover silt and Kelovey sandy loam. The failure activation energy was expressed as a function of the rheological parameters of the long-term strength equation in the form of the sum of two components: an initial value that is independent of failure stress and a stress-dependent increment of the activation energy. The analysis showed that the initial value of the failure activation energy varied between the limits of 10.4 and 19.4 kcal/mole, the variation of stress-dependent increments was between 0.3 and 6.6 kcal/mole,

and the sum varied from 12.9 to 19.7 kcal/mole. The smaller initial and sum values of the activation energy refer to the clay soils and the greater values to the sandy soils.

FROZEN GROUND STRENGTH, GROUND WA-TER, WATER CONTENT, STRESS STRAIN DIA-GRAMS, COMPRESSIVE PROPERTIES, GROUND ICE, LOADS (FORCES), GRAIN SIZE. GROUND ICE, LOADS (FORCES), GRAIN SIZE. A total of 45 unconfined compression tests were conducted on frozen specimens of remolded, saturated Fairbanks silt at dry unit weights ranging from 993 to 1490 kilograms per cubic meter with total water contents ranging from 0.28 to 0.58. The rotal water contents ranging from the criterion that the ice matrix in the soil fractures at the first point of significant yield shown in the stress-strain curve, which occurs at less than 0.01 strain in this study, the "ice matrix strength" is shown to be nearly proportional to the volumetric ice content of the soil for these tests. The strength at 0.2 strain appears to be nearly independent of the dry unit weight and water content of the soil.

(MASS/VOLUME), SOIL STRUCTURE.
Settlement of clay soils after freezing and thawing is the
result of the suction forces that draw pore water to the
freezing front. These suction forces cause an increase
in the effective stress on the clay beneath the freezing
front, and thus cause an overconsolidation of the clay. As
these suction forces often exceed 1 atmosphere, their direct
measurement is not easy. The volume changes resulting
from the freezing and thawing of clays are related to the
plastic limit and have been observed in the laboratory to
be as high as 25%. If provisions are not made to account
for these volume changes in a ground freezing project, considerable damage to structures can occur from settlement and
the resulting stresses.

PERIMENTATION, FATIGUE (MATERIALS). This paper describes a method of computing the ice force and response of the structure on the basis of information given for ice velocity and properties of ice and the structure. The method is a step-by-step procedure using mode shape analysis involving two basic phases. During the first phase the structure penetrates into the ice sheet until a random loading rate dependent ice strength is reached. The ice sheet then fails within an area with finite length. Both the penetration and the failed zone are assumed to depend linearly on force. The ice forces and structural responses have been computed for a test structure at the U.S. Army Cold Regions Research and Engineering Laboratory in Hanover, New Hampshire, and the results are found to be consistent with those sectually measured in laboratory experiments.

A sea ice model which employs a viscous-plastic constitutive law has been applied to the East Greenland area. The model is run on a 40-km spatial scale at 1/4 day time steps for a 60-day period, using forcing data beginning 1 October 1979. Preliminary results verify that the model predicts reasonable thicknesses and velocities well within the ice margin. Separate simulations show that thermodynamics only and free drift with thermodynamics produce inadequate results. In particular, the free drift simulation produces unrealistic ice trajectories with excessive drift toward the coast and unreasonable nearshore thicknesses. The net results of these simulations tend to verify that internal

POOLING OF OIL UNDER SEA ICE.

los thickness profiles were constructed for six fast ice locations in the vicinity of Prudhoe Bay, Alaska, using a radar echo acunding system. The sounding data revealed in detail the undulating relief of the bottom of the sea ice in which oil could pool up if released under the ice. In general, ice bottom morphology was found to reflect variation of the surface snow cover thickness and ice deformation. However, at several sites the ice bottom relief could not be correlated with these factors. Slush ice accumulations of up to 0.5 m were apparently the cause of this bottom roughness. Retimates of the volume of oil that could need up in the ice bottom relief range from 20,000 to 60,000 roughness. Batimates of the volume of oil that could pool up in the ice bottom relief range from 20,000 to 60,000 ca m/sq km. For undeformed fast ice with no bottom about 10,000 to 35,000 cu m/sq km. The effect of slush ice relief and structure on potential under-ice oil pooling is for the most part unknown.

Information on sea ice conditions in the Bering Strait and
the losfloot formation around Fairway Rock, located in the
strait, is presented. Cross-sectional profiles of Fairway
Rock and the relief of the locfloot are given along with
theoretical analyses of the possible forces active during locfloot
formation. It is shown that the loc cover most likely
falls in flexure as opposed to crushing or buckling, as the
former requires less force. Field observations reveal that
the Fairway Rock ioeffoot is massive, with ridges up to
15 m high, a seaward face only 20 deg from vertical, and
interior ridge slopes averaging 33 deg. The icefoot is
believed to be grounded, and its width ranges from less
than 10 to over 100 meters.

The contribution of brine layers to observed reflective anisotropy of sea ice at 2100 MHz is quantitatively assessed, and a theoretical explanation for observed reflective anisotropy is proposed in terms of anisotropic electric flux penetration into the brine layers. The sea ice is assumed to be a stratified dielectric consisting of prue ice containing ellipsoidal conducting inclusions (brine layers) uniformly aligned with their long axes perpendicular to the preferred crystallographic c axis direction. The symmetrical geometry of the brine layers is shown to produce an anisotropy in the complex dielectric constant of sea ice. The contribution of these layers to the reflective anisotropy is examined with a numerical method of approximating the reflected power of a radar pulse incident on a slab of sea ice. (Auth. mod.)

EMATICAL MODELS, SOIL WATER.

An analytical procedure is developed for the determination of potentiometric head in nonhomogeneous aquifers. Both steady and unsteady flow conditions are considered. The analytical procedure is based upon the use of orthogonal functions. It consists essentially of assuming an appropriate orthogonal series for both the aquifer properties and the unknown potentiometric head. The technique is applied to several one- and two-dimensional flow problems where conditions are described by the linearized Bouseinseq equation. The result of the analysis is the expression of potentiometric heads in analytic form. Subsequent use of Darcy's law yields accurate, enalytic equations for the associated velocity fields. Such representations of the flow field are a potential benefit for prediction of mass transport in groundwater since velocity is known as a continuous function of space and time. Other useful features of the orthogonal series approach include its straightforward application. The approach is include its straightforward application. The app also shows to eliminate the introduction of discr errors associated with the use of node systems wh required by many alternative numerical methods.

SEA ICE, GROUND ICE, ICE ELECTRICAL PROPERTIES, RADAR ECHOES, SUBSURFACE INVESTIGATIONS, WAVE PROPAGATION, ELECTRIC FIELDS, MATHEMATICAL MOD-ELS, DIELECTRIC PROPERTIES.

ELS, DIELECTRIC PROPERTIES.

The propagation of subsurface radar pulses in complex dielectric media is studied numerically. The model waveform is a 10-ns sinusoidal cycle, and the media properties are similar to those of moist ground or see ice. When the real part of the dielectric permittivity is frequency independent and the imaginary part is dominated by the dc resistivity, amplitudes of the positive and negative half cycles unbalance, and the sinusoidal zero crossing is delayed from its normal position. In these cases, if reflector depth is known, the dielectric constant can be measured from the time delay of the leading edge of the signal, and the dc resistivity can be estimated from a comparison of the input and output pulse power spectra. When dielectric permittivity is frequency dependent through a simple relaxation process, waveform distortion depends on relaxation frequency. In addition, if reflector depth is known, the dielectric relaxation parameters may be estimated when the medium relaxation process, waveform the subsequency its above and below the major portion of the pulse bandwidth, respectively.

FROST HEAVE, HEAT TRANSFER, SOIL WATER MIGRATION, PROST PENETRATION, TEMPERATURE EFFECTS, MATHEMATICAL MODELS.

MODELS.

A one-dimensional model for simulation of frost heave in a vertical soil column is preented. The model is based on simulaneous computation of heat and moisture transport in a freezing or thawing soil. Thermal processes at the freezing front are approximated by a lumped isothermal approach. The model accurately simulates frost heave, soil pore-water pressures, and temperatures when compared with a laboratory freezing column; however, to achieve adequate correlation certain model parameters must be determined by calibration. Because the model, like the frost-heave process itself, is highly sensitive to environmental and soil parameters that are variable in both time and space, purely deterministic simulations will not provide sufficiently accurate predictions. Consequently, further development of the model is required in order to include a statistical-probabilistic approach for estimating frost heave within specified confidence limits.

FROST ACTION, FROZEN GROUND MECHAN-ICS, FREEZE THAW TESTS, SOIL WATER, SOIL TEMPERATURE, WATER CONTENT, MATH-EMATICAL MODELS.

EMATICAL MODELS.

The use of an instrumented soil column in tests to develop a mathematical model of the frost-heave process is described. Tensiometers, heat-flow meters, thermocouples, and electrical resistivity gages were installed throughout a soil column filled with Pairbanks siit, Chena Hot Springs siit, or West Lebanon gravel. The column was 100 cm long and about 14 cm in diameter. An open system was used and absorption was monitored during the freezing process. Tests were conducted by using a constant rate of frost penetration, a constant heat-flow rate, or three sequentially lower temperature step changes at the soil surface. The soil column has provided critical data for verification of a one-dimensional mathematical model for estimating frost heave. As more soils are tested, this equipment will assist in improving and

developing algorithms for the mathematical model and the most critical parameters that affect frost heave to a given soil-e.g., surcharge, free water level, and hydraulic conductivity. A procedure is also presented for determining the saturated and unsaturated hydraulic conductivity and moisture-retention characteristics of a soil.

COMPARATIVE EVALUATION OF FROST-CHARGE TRAILITY EVALUATION OF FROST-SUSCEPTIBILITY TESTS. Chamberlain, E.J., Transportation research record, 1981, No.809, p.42-52, 89 refs.

SOIL FREEZING, SOIL WATER, FROST RESISTANCE, FROST HEAVE, GROUND ICE, FREEZE THAW TESTS, FROST ACTION, GRAIN SIZE, PARTICLE SIZE DISTRIBUTION.

PARTICLE SIZE DISTRIBUTION.

Methods of determining the frost susceptibility of soils are identified and presented. More than 100 criteria were found; the most common were based on particle-size characteristics. These particle size criteria are frequently sugmented by information such as grain-size distribution, uniformity coefficients, and Atterberg limits. Other types of information, such as permeability, mineralogy, and soil classification, have also been required. More complex methods that require tests based on pore-size distribution, moisture tension, hydraulic conductivity, heave streas, and frost heave have also been proposed. However, none has proved to be a universal test for determining the frost susceptibility of soils. Based on this survey, four methods are proposed for further study: the U.S. Army Corps of Engineers Prost-Susceptibility Classification Systems, the moisture-tension/hydraulic-conductivity test, a new frost-heave test, and the California bearing ratio after-thaw test.

36-1866

PRAZIL ICE, ICE FORMATION, ICE ACCRETION, ICE GROWTH, WATER FLOW, ICE COVER STRENGTH, RIVER ICE, NUCLATING AGENTS, ICE BOOMS.

AGENTS, ICE BOOMS.

A preliminary investigation was made of the effect of frazil ice on arrays of lines positioned in flowing water under winter conditions. It was found that the lines would provide a stable basis for forming an ice cover on many stream reaches that would normally remain open because of high velocity and shallow depths.

Tests were conducted in a refrigerated flume and in small mountain rivers. Plume depths varied from 2-22 cm and river depths varied from 2-22 cm and river depths varied from 2-0.04 m/s in the flume and a range of 0.6-0.8 m/s in the rivers. Prazil ice would grow on a line quite rapidly achieving a diameter of 32 mm in 15 min, on a 3.2 mm dia line in the flume. In the river, overnight accumulations reached 20 cm in depth. A few drag force measurements were made which yielded an average shear drag coefficient of 0.16. The results suggest methods of increasing our control over ice. control over ice.

MP 1489 ONE-DIMENSIONAL TRANSPORT FROM A HIGHLY CONCENTRATED, TRANSPER TYPE SOURCE.

O'Neill, K., International journal of heat and mass transfer, 1982, 25(1), p.27-36, With French, German and Russian summaries. 27 refs. 36-1863

HEAT TRANSFER, MASS TRANSFER, PLOW RATE, ANALYSIS (MATHEMATICS).

In both heat and mass transfer, situations arise in which an entity considered as a source/sink has strength which can only be expressed in terms of an unknown rate of source—flow field transfer. This occurs when transfer between the source and medium is driven by a dependent variable difference which is unknown, because the responding medium value is unknown. Manifold mathematical complexities arise when in addition the source is highly concentration.

ed spatially relative to the size of the overall domain. A 1-dim convective-diffusive transport equation suitable for this cause may be solved by simultaneous use of the Pourier transform and its inverse in the same equation, together with other transformation and manipulation. From the solution obtained for the case of constant source intensity, one may construct a general expression for the solution when source intensity varies arbitrarily in time. Explicit expressions are obtained for solution of the fundamental case of temporally sinusoidal source intensity.

OMETRY, AIRBORNE EQUIPMENT.

An airborne spectroradiometer with 500 parallel channels has been used to monitor water quality in various water environments. Field experiments were run to test and evaluate the instrument's response to various amounts of suspended materials in water. Procedures were evaluated in the laboratory to separate the various components from the total reflected radiance and to correlate the pectral distribution of the subsurface reflectance to the organic/inorganic materials in the water. It was concluded that qualitative and quantitative measurement of turbidity within a water body is possible using the airborne spectroradiometer. The accuracy of the quantitative measurement is still under investigation, but suspended sediment concentration of less than 3 prim can be detected. Organic and inorganic constituents can be qualitatively differentiated.

FULL-DEPTH AND GRANULAR BASE COURSE DESIGN FOR FROST AREAS.

LOADS, DEFORMATION.

When properly designed and constructed, the Asphalt Institute full-depth pavement concept can be a viable design alternative for seasonal frost areas. The Corps of Engineers reduced subgrade strength frost design proved to be an upper bound or conservative design under these test conditions. For each design, two different thickneases were studied in the set sections placed over 12 in. of prepared subgrade and tested under light traffic conditions in Hanover, New Hampshire. After design traffic loading was exceeded, pavement failure occurred as expected in the thinner full-depth section. The thinner reduced subgrade strength section was still in good condition after experiencing twice its design loading. Frost penetrations, pevement n-factors (surface transfer coefficients), Benkelman Beam deflections, and the spring subgrade moisture contents are also compared for the two designs.

ANALYSIS (MATHEMATICS).

An approximate solution to the Neumann problem has been obtained by using the heat balance integral method. The accuracy of the solution is shown to be very good for all practical soil systems cases. The thermal properties of soil systems are also expressed in terms of only the liquid volumetric fraction and combine with the approximate solution to give a rapid, accurate solution for freeze/thaw problems without using graphs, tables, or transcendental equations. A simple relation is also given for the analogous problem in cylindrical coordinates, but its range of validity is somewhat limited.

ACOUSTIC EMISSIONS DURING CREEP OF FROZEN SOILS.

GROUND PHYSICS, FROZEN GROUND STRENGTH, SOIL CREEP, ACOUSTICS, RHEOLOGY, STRESSES, COMPRESSIVE PROPERTIES, SOIL FREEZING, DEFORMA-

TION.

Deformation, time-dependent failure, and acoustic emissions during unconfined compression tests of frozen Fairbanks silt were studied. Acoustic emissions (AE) are detected when the applied stress exceeds a threshold level. This threshold stress is related to the limit of long-term strength of the frozen soil. Under stress exceeding the limit of the long-term strength, the accumulation of acoustic emissions with time can be correlated with creep deformation; that is, plots of the cumulative number of acoustic pulses versus time have shapes similar to those of creep curves with primary, secondary, and tertiary stages. Such correspondence made it possible to describe both phenomena from the viewpoint of the unified kinetic theory of strength. Experimental data are presented, and unified constitutive equations describing deformations, time-dependent failure, and the accumulation of the acoustic emissions during short-term creep of frozen soils are derived. The time to incipient failure, when the AE rate reaches a minimum, is considered to be the most important characteristic of a creep process. It is shown that this time can be predicted theoretically if the parameters of the AB process and the stress state of the frozen soil are known.

MP 1496

MP 1496 PHASE CHANGE AROUND INSULATED BU-

RIED PIPES: QUASI-STEADY METHOD. Lunardini, V.J., Journal of energy resources technology, Sep. 1981, Vol.103, p.201-207, 13 refs. 36-2401

FREEZE THAW TESTS, UNDERGROUND PIPE-LINES, HEAT TRANSFER, STEFAN PROBLEM, PHASE TRANSFORMATIONS, PIPELINE INSU-THERMAL INSULATION, ANALYSIS (MATHEMATICS).

The heat transfer problem for cylinders embedded in a medium with variable thermal properties cannot be solved excatly if phase change occurs. Approximate solutions have been found using the quasi-steady method. The temperature field, phase change location, and pipe surface heat transfer can be estimated using graphs presented for parametric ranges of temperature, thermal properties, burial depth, and insulation thickness. The accuracy of the graphs increases as the Stefan number decreases and they should be of particular value for insulated hot pipes or refrigerated gas lines.

HIGHLY EFFICIENT, OSCILLATION FREE SO-LUTION OF THE TRANSPORT EQUATION OVER LONG TIMES AND LARGE SPACES. O'Neill, K., Water resources research, Dec. 1981, 17(6), p.1665-1675, 28 refs. 36-2428

VENTING OF BUILT-UP ROOFING SYSTEMS. Tobiasson, W., Conference on Roofing Technology, 6th, Gaithersburg, MD, Apr. 30-May I, 1981. Proceedings, 1981, p.16-21, 12 refs. 38-3981

ROOFS, VENTILATION, THERMAL INSULA-TION, MOISTURE, DRYING, DRAINS, VAPOR

Table 1 summarizes the information presented in this paper. The following rules of thumb are offered: 1. Bituminous built-up membranes should be vented during construction to allow excess moisture to dissipate. 2. Do not rely on venting above wet-applied decks or wet-applied insulations to dry them. 3. Allow wet-applied decks and wet-applied insulations to dry into the space below. 4. To make roofing systems less vulnerable to moisture problems avoid using moisture-sensitive materials for the bottom ply of a membrane. 5. There is no reason to vent the insulation of a roof lacking a vapor retarder. In fact, venting such roofs may do more thermal and moistitu- harm than good. 6. When a vapor retarder is required, focus money and efforts that might be spent on vents to improving the quality of the vapor retarder. 7. Do not expect to be able to encapsulate insulation in a vapor tight, pressurizable envelope. Consequently, do not worry too much shout creating excess pressures within the roofing system (except within the membrane itself). 8. Do not expect to be able to dry out wet insulation in compact roofs by venting. 9. Some drying of wet fibrous glass insulation is possible by draining away water.

PERATURE EFFECTS, TESTS.

The CRREL frost heave test for determining the frost susceptibility of soils and granular base materials is described. The CRREL test is conducted with a constant rate of frost penetration of 1.3 cm/day with water freely availale. The frost susceptibility classification system is based on the average rate of heave for 12 days. A summary of nearty 400 tests is given to show the wide range of results for similar materials. A summary of the U.S. Army Corps of Engineers Prost Design Classification System is also given to show for what materials the frost heave test is required.

OVERVIEW OF SEASONAL SNOW METAMOR-

Colbeck, S.C., Reviews of geophysics and space physics, Feb. 1982, 20(1), p.45-61, 43 refs., Presented at the U.S.-Canadian Workshop on the Properties of Snow, Snowbird, Utah, April 8-10, 1981.

SNOW PHYSICS, METAMORPHISM (SNOW), SNOW COVER STRUCTURE, SNOW WATER CONTENT.

CONTENT.

The grains in seasonal anow undergo rapid and radical transformations in size, shape, and cohesion. These grain characteristics affect all of the basis properties of anow. Snow is characterized as either wet or dry depending on the presence of liquid water. Wet snow is markedly different at low and high liquid contents. Dry snow is characterized as either an equilibrium form or a kinetic growth form; that is, it is either well rounded or faceted. Of course, many snow grains display either transitional features between two of these categories or features which arise from other processes. Snow is classified depending on the dominant processes of its metamorphism.

EL, AERIAL SURVEYS, HISTORY.

The objectives of this investigation were to analyze past patterns of shoreline change, estimate the amounts of change in the positions of the high water line and sea cliff break and base, and estimate rates of accretion and erosion. Distances from selected reference points to the high water line, cliff break, and cliff base were measured using photointerpretation techniques on black and white 9 x 9 in serial photographs acquired in 1938, 1952, 1971 and 1974. The amounts and rates of change are calculated for the intervals between the dates of photo acquisition and for the total period from 1938 to 1974.

SHORELINE MODIFICATION, SHORE ERO-SION, PHOTOINTERPRETATION, AERIAL SURVEYS, PHOTOGRAMMETRY. AERIAL

SURVEYS, PHOTOGRAMMETRY.

The protection and preservation of shorelines and coastal areas along oceans, lakes, reservoirs and rivers have become increasingly important with more intensive use and development of these areas by the growing population. Shoreline crossion and subsequent shoreline recession are of primary concern since they cause property loss, changes in shoreline habitats and degraded water quality. USACRREL has been investigating many of the complex erosion processes, site spec for rates of erosion and problems caused by shoreline erosion. As an integral part of these comprehensive investigations, historical and recent serial photographs have been used to document historical shoreline characteristics and conditions, to determine past patterns of regional shoreline changes, to monitor the areal extent of shoreline erosion, and to estimate the historical rates of change in shoreline positions.

DRYING, VENTILATION, VAPOR BARRIERS.

Nondestructive techniques are being widely used to locate wet insulation in compact roofing systems. Now that wet insulation can be found, breather vents and so-called 'breathable' membranes are being promoted to dry out wet insulation, thereby recovering its thermal effectiveness. Our exposure tests in New Hampshire indicate that the above venting methods are all rather ineffective in drying sealed specimens of pertite and fibrous glass roof insulation. It would take many decades to dry our specimens at the rate we measured over the past two years. Cross-ventilation within the insulation increased the rate of drying. For peritie insulation, the faster rate would still result in a drying time measured in decades. For fibrous glass insulation, the drying time was reduced to 13 years. We have succeed in drying fibrous glass insulation in a roof by removing the water with a vacuum cleaner.

TATION.

The configuration and fabrics of ice in frozen glass beads and sands with a low initial water content were observed. As suggested by Miller, the air-ice interface is convex, and pores seem to fill unstably. This produces an uneven ice distribution when the water supply is limited. Many different ice shapes and crystal distributions were observed, indicating a mixture of kinetic crystal growth processes and equilibrium constraints. Ice dendrites arose from rapid growth.

Both single and multicrystalline structures were found. Clearly, a wide variety of situations is possible, depending on growth rates, nucleation sites, and local paths of heat and mass flow.

MP 1513 SOME FIELD STUDIES OF THE CORRELA-TION BETWEEN ELECTROMAGNETIC AND DIRECT CURRENT MEASUREMENTS OF GROUND RESISTIVITY.

TRIC FIELDS, GROUND ICE.

Electromagnetic (em) and direct-current (d-c) methods of measuring ground resistivity have been compared at permafrost and nonpermafrost sites. The em methods utilized the principles of magnetic induction and plane wave surface impedance. Layered ground models were derived from the d-c sounding data, and the theoretical values of the em methods for these models were compared with the em field results. Both em methods correlated well with the control of large extent. In several cases of resistive inhomogeneities,

the magnetic induction data correlated well with the de data. In one case of a resistive inhomogeneity, the surface impedance responded well only qualitatively and may have given some false indications of resistive substructure. have given some false indications of resistive substructure. It appears that in all cases where the volume of exploration was comparable, there was reasonable correlation. It is estimated that the standard data analysis procedure which assumes layering of infinite extent will apply well for the surface impedance method when disturbances in the local layering are greater than a skin depth away from the point of measurement; and for the magnetic induction method when disturbances in the layering are at a distance from the interloop axis that is greater than the interloop separation.

COMPUTER APPLICATIONS.

The U.S. Army Cold Regions Research and Rugineering Laboratory has recently acquired an instrumented vehicle for the measurement of forces at the tire/surface material interface. The CREL instrumented vehicle (CTV) is equipped with moment-compensated triaxial load cells mounted in the front wheel assemblies. Forces are measured in the vertical, longitudinal (in the direction of motion) and side directions. In addition, accurate wheel and vehicle speeds and rear axle torque and speed are measured. Modifications to the vehicle to facilitate the performance of traction and motion resistance tests include four lock-out type hubs to allow front, rear- or four-wheel drive and a dual brake system for front-, rear- or four-wheel braking. A minicomputer-based data acquisition system is installed in the vehicle to control data collection and for data processing, analysis, and display. Discussion of the vehicle includes its operation and use for the evaluation of the tire performance and surface material properties of motion resistance and traction.

RUBBER SNOW FRICTION, SNOW SURFACE, TRACTION, VEHICLES, ANALYSIS (MATH-EMATICS).

EMATICS). Research on vehicle mobility in snow has recently become significantly updated by the use of instrumented vehicles. Utilizing triaxial load cells in the front wheel assemblies, the vehicles are capable of measuring the traction and motion resistance forces located at the tire/snow interface. Based on these measured quantities, snow surface characterization parameters are developed. Also, using an energetics approach, a tire performance parameter is developed which offers a measure of the slip-shear energy expended by a tire moving a unit distance. This paper presents the methods, equipment and philosophy followed by the authors in evaluating tire performance in a shallow snow cover. Definitions of terms are contained in the Appendix.

ON THE DIFFERENCES IN ABLATION SEA-SONS OF ARCTIC AND ANTARCTIC SEA ICE. Andreas, E.L., et al, Journal of the atmospheric sciences, Feb. 1982, 39(2), p.440-447, 41 refs.

SEA ICE, ICE MELTING, ABLATION, METEOROLOGICAL FACTORS.
Arctic sea ice is freckled with melt ponds during the ablation season; Antarctic sea ice has few, if any. On the basis of a simple surface heat budget, the authors investigate the meteorological conditions necessary for the onset of surface melting in an attempt to explain these observations. The low relative humidity associated with the relatively dry winds off the continent and an effective radiation parameter smaller than that characteristic of the Arctic are primarily responsible for the absence of melt features in the Antarctic. Together these require a surface-layer air temperature above OC before Antarctic sea ice can melt. A ratio of the bulk transfer coefficients less than 1 slac contributes to the dissimilarity in Arctic and Antarctic ablation seasons. The effects of wind speed and of the sea-ice roughness

on the absolute values of bulk transfer coefficients seem to moderate regional differences, but final assessment of this hypothesis awaits better data, especially from the Antarctic. (Auth.)

SHEDS, STATISTICAL ANALYSIS.
Sediment load in low-order streams of the unglaciated Yukon-Tanuna Uplands of central Alaska may be related to drainage basin characteristics and to stream channel morphology. This has been investigated by analysis of selected physical hydrological and water quality data for the 104 sq km Caribon-Poker Creeks Research Watershed, located at 65 deg, 09 min N, 147 deg, 30 min W in a region of rolling to steep uplands and discontinuous permatirost. Channel morphology data are available for first-, second- and third-order streams. Sediment load for selected points was determined over 45 weeks during summer of 1978 and 1979. Consistent differences in sediment yield, hydrologic regime and channel morphology have been determined between permafrost and non-permafrost drainages.

SLOPE.

The U.S. Army Cold Regions Research and Engineering Laboratory (USA CRREL) has long conducted research in snow, ice, and permafrost. It also translates foreign language engineering papers and publishes research reports, monographs, and bibliographies. Snow and ice roads and construction pads have been used, primarily on the Arctic Slope, during the last few winters. Some have been successful but problems exist which will require further experience and research to solve. One problem is that of snow supply. Snowfall on the Arctic Slope is limited, particularly early in the season when it is most desired. Pew good data are available on total quantities and the time pattern of snowfall but Wyoming Snow Gages, now being installed by a number of government agencies and private organizations, are beginning to provide some data which can be used with some confidence. The snow which falls is often blown off by the strong winds which are common in the area so it is not available where it is needed. Research is under way on equipment and techniques for collecting snow and inducing drifting.

STATES—ALASKA—NORTH SLOPE.

Peak shock pressures in frozen soil resulting from underground explosions of moderate size and their effect on fish populations are examined, based on current knowledge of shock pressure patterns and the sensitivity of fish eggs and young and adult fish to such pressures. The peak shock pressures attenuate rapidly with distance from explosions and it appears that moderate-sized explosions, such as those from standard sciamic shots, can be fired within a few hundred feet of water bodies without exceeding allowable peak shock pressures in the water bodies. Experimental studies should be carried out to confirm the pattern of peak shock pressure attenuation and examine the effectiveness of shock transmission between frozen ground and the water bodies.

Results of an experiment performed at drifting ice station FRAM I in the Arctic Ocean northwest of Spitzbergen during March-May 1979 indicate that sensible heat flux from the ocean to the ice cover was less than 2 W/sq.m. The estimate is based on measurements of temperature gradient, growth rate, and salinity of young sea ice. Uncertainty in the magnitude of the heat flux results more from evidence of horizontal inhomogeneity in the growing ice sheet than from measurement errors.

EMATICAL MODELS, MECHANICAL TESTS.
The acoustic emission response from fine-grained polycrystalline ice subjected to constant compressive loads was examined.
A number of tests were conducted with the nominal stress
ranging from 0.8 to 3.67 MPa at a temperature of -5C.
The acoustic emission response was recorded and the data
are presented with respect to time and strain. The source
of acoustic emissions in ice is considered in terms of the
formation of both microfractures and visible fractures that
develop without catastrophic failure of the ice. A model
to describe the acoustic emission response is developed.

VELOCITY, ICE STRENGTH.

The behavior of an ice dynamics model employing a viscous plastic rheology is investigated. Time and space scales of the order of 3 hours and 20 km are emphasized. However, whenever possible the results are presented in a nondimensional form. Numerical parameter variations examined include the effect of the "rigid" creep rate on numerical convergence rate, the effects of ice strength on the numerical adjustment time needed to fully attain ideal plastic flow, and the effect of grid size on the behavior of simulated ice dynamics. Based on the results of these studies a viable numerical procedure for simulating mesoscale plastic flow is proposed.

(MATHEMATICS).

Air bubbler systems are used to suppress ice formation and prevent ice damage to structures. Injection of air into the slightly more dense, warm water at the bottom of a body of fresh water raises the warm water to the surface. A bubbler system provides a simple and inexpensive means of suppressing ice if the body of water has the necessary thermal reserve. A study was conducted with a point source bubbler to examine its performance when installed under an existing layer of thick lake ice.

SEA ICE DISTRIBUTION, DRIFT, ICE GROWTH, THERMODYNAMICS, MATHEMATICAL MOD-ELS, GREENLAND.

A dynamic-thermodynamic sea ice model which employs a viscous-plastic constitutive law has been applied to the

Bast Greenland area. The model is run on a 40-km spatial scale at 1/4-day time steps for a 60-day period with forcing data beginning on Oct. 1, 1979. Results tend to verify that the model predicts reasonable thicknesses and velocities within the ice margin. Thermodynamic ice growth produces excessive ice extent, however, probably due to inadequate parameterization of oceanic heat flux.

ICE CRYSTAL MORPHOLOGY AND GROWTH RATES AT LOW SUPERSATURATIONS AND HIGH TEMPERATURES.

ICE CRYSTAL STRUCTURE, ICE CRYSTAL GROWTH, SUPERSATURATION, TEMPERATURE EFFECTS, VAPOR DIFFUSION, DENSITY (MASS/VOLUME), MATHEMATICAL MODELS (MASS/VOLUME), MATHEMATICAL MODELS.
At an excess vapor density (supersaturation of about 1/10,000) adjacent to the ice crystal surface of 50-60 billionth g/cc, there is a transition between the highly faceted kinetic growth form and the rounded equilibrium form at temperatures above -6C. At lover temperatures there is a transition in the equilibrium form to hexagonal prisms because of a reduction in the disordered surface layer. The growth rate of ice crystals from the vapor is analyzed by a simple model which accounts for vapor flow and surface processes separately. The conditions for highly temperature sensitive growth are identified from the model.

POR, TEMPERATURE EFFECTS.

The early stages of ice crystal formation in supercooled fogs were studied in detail by electron microscopy, and ice nucleation experiments using liquid propane seeding were conducted in a thermostatically controlled coldroom. Ice crystals, formed by rapid cooling created by the evaporation of liquid propane from a fine nozzle at temperatures from -0.1 to -40C, were collected and replicated on filmed grids for electron microscope examinations. Most of the ice crystals formed immediately after the liquid propane seedings were spherical (although approx. 20% were hexagonal) with diameters ranging from 0.3 to 3 micrometer and with a mean diameter of 1.5 micrometer. Electron microscopy revealed a grain boundary in some of the ice crystals. MP 1540

—VOSTOK STATION.

This report emphasizes aitrate ion (NO3) concentrations in antarctic snow and firm from pits and cores. Chemical analyses conducted or planned on antarctic snow, firm, and cice are outlined. Computer curves compare the variation in NO3 over the past 1,000 yr in firm cores from South Pole Station and Vostok and present the NO3 concentration record for the entire Vostok core over the past 3,000 yr. South Pole firm core dates have been calculated using data which date back to 1750. Fourier analysis of the NO3 data from both South Pole and Vostok cores reveals strong periodicities in the NO3 concentration occurring at approx 11-, 22-, and 66-yr intervals. Data have previously been

reported supporting the hypothesis that the 11-yr fluctuations in NO3 either coincide with the solar activity max or the auroral max. A table lists 14 potential sources or mechanisms for NO3 in antarctic snow or firm. Solar-mediated phenomena appear to be the more likely sources. The results of NO3 sampling in a 10-m-deep snowpit are discussed.

ROLE OF PLASTIC ICE INTERACTION IN MARGINAL ICE ZONE DYNAMICS.

Leppäranta, M., et al, Journal of geophysical research, Nov. 20, 1985, 90(C6), p.11,899-11,909, 17 refs. Hibler, W.D., III. 40-4615

ICE EDGE, SEA ICE, ICE COVER THICKNESS, PLASTIC FLOW, WIND DIRECTION, WIND VELOCITY, ICE MODELS.

VELOCITY, ICE MODELS.

Under appropriate conditions, the nonlinear nature of plastic ice interaction together with a nonlinear coupling between ice thickness characteristics and ice rheology can substantially modify the character of marginal ice zone dynamics. This paper examines the steady state ramifications of these nonlinearities by using a one-dimensional simplification of a two-level viacous plastic sea ice model. A series of idealized small-scale simulations (4-km resolution) is carried out with the model. small-scale simulations (4-km resolution) is carried out with the model formulated in a moving Lagrangian grid in order to remove diffusion effects. Analytic solutions for the equilibrium plastic adjustment case are also constructed. The results show that if the ice thickness distribution is allowed to equilibrate in response to a constant wind field, the thickness strength coupling will yield a sharp ice edge, with the compactness dropping rapidly to zero near the ice margin. GEOMETRY AND PERMITTIVITY OF SNOW

AT HIGH FREQUENCIES.
Colbeck, S.C., Journal of applied physics, June 1982, 53(6), p.4495-4500, 37 refs.
36-3921

36-3921 SNOW ELECTRICAL PROPERTIES, SNOW DENSITY, POROSITY, SNOW CRYSTAL STRUC-TURE, SNOW PHYSICS, TEMPERATURE GRADIENTS, LIQUID PHASES, WET SNOW, DIELECTRIC PROPERTIES.

The geometry and porosity of dry snow varies widely depending on the history of conditions. The permittivity of dry snow increases with increasing ice content but is not greatly affected by the shapes of the ice particles. In wet snow the permittivity increases with liquid content and the geometry is very important. However, the liquidlike layer has little

effect on permittivity. The permittivity is described using Polder and van Santen's mixing formulae and approximations of the geometries at high and low liquid contents. It is shown that the common assumption of liquid shells over ice spheres is both physically incorrect and leads to large

DIELECTRIC PROPERTIES, ACTIVE LAYER, GROUND THAWING, PERMAFROST BASES, RADAR ECHOES.

RADAR ECHOES.
Field measurements of the dielectric constant of thawed active layers of up to 1 m in depth at four sites in Alaska have been made using short-pulse ground radar whose returns were received in the near-field radiation zone. Three sites consisted of saturated silts with varying amounts of organic material, and the fourth site was a moist sand. The reflector returning the radar signals was the active layer/permafrost interface. Analysis of the waveforms showed that all the materials were nondispersive over the radar pulse bandwidth (75-225 MHz), and this was confirmed by time domain reflectometry (TDR) studies of field samples. The average dielectric constants were between 23 and 34 for the silts, which averaged between 45 and 50% water by volume, while the sandy site gave an average value of about 12 for a probable water content of about 23% by volume. These values are very similar to the laboratory work of others and were also confirmed by TDR. The high dielectric constants of the saturated materials allowed accurate profiling of active layer depth, and an example is presented. More detail would probably be achieved with a higher-frequency radar.

ON MODELING THE WEDDELL SEA PACK

Hibler, W.D., III, et al, Annals of glaciology, 1982, Vol.3, International Symposium on Antarctic Glaciology, 3rd, Columbus, Ohio, Sep. 7-12, 1981, p.125-130, 23 refs.

Ackley, S.F. 37-259

SEA ICE, PACK ICE, THERMODYNAMIC PROP-ERTIES, ICE MODELS, ANTARCTICA—WED-

DELL SEA.

Some results from a dynamic-thermodynamic simulation of the sessonal cycle of the Weddell Sea pack ice are described. The model used for the study is similar to that developed for a numerical investigation of the Arctic ice cover. It employs a plastic ice rheology coupled to a two-level ice thickness distribution. The thickness characteristics evolve in response to ice dynamics, and to ice growth and decay rates dictated by surface heat calculations and by heat storage in a fixed depth oceanic boundary layer. Observed time-tarying wind, temperature, and humidity fields are used together with empirical radiation fields and fixed ocean currents to drive the model. Employing these fields, the model

is integrated over two seasonal cycles. Overall, the results suggest that (1) ice dynamics are essential in describing the seasonal cycle, and (2) a feedback between the atmospheric temperature and the presence of ice may be a major cause of the rapid decay of the Antarctic ice cover during the spring-summer period. BRINE ZONE IN THE MCMURDO ICE SHELF, ANTARCTICA

Kovaca, A., et al, Annals of glaciology, 1982, Vol.3, International Symposium on Antarctic Glaciology, 3rd, Columbus, Ohio, Sep. 7-12, 1981, p.166-171, 21

Gow, A.J., Cragin, J.H.

ICE SHELVES, BRINES, MIGRATION, ANTARCTICA—MCMURDO ICE SHELF.

TICA—MCMURDO ICE SHELF.
Infiltration of brine into the McMurdo Ice Shelf is dominated by wave-like intrusions of sea-water triggered by periodic break-outs of the ice front. Observations of a brine step 4.4 m in height in the McMurdo Ice Shelf show that it has migrated about 1.2 km in four years. The inland boundary of the brine percolation is probably controlled largely by the depth at which brine encounters the firn/ice transition (43 m). However, this boundary is not fixed by permeability considerations alone, since measurable movement of brine is still occurring at the inland boundary. Freeze-fractionation of the sea-water as it migrates through the ice shelf pracipitates virtually all sodium sulfate, and preferentially concomitant removal of water by freezing in the pore spaces of the infiltrated firm produces residual brines approximately seven times more concentrated than the original sea-water. SNOW COMPOSITION, SNOW IMPURITIES, PERIODIC VARIATIONS, NITRATE DEPOSITS, ANTARCTICA—EAST ANTARCTICA.

ANTARCTICA—EAST ANTARCTICA.

Data are summarized on in situ nitrate ion concentrations in anow pits and firn cores over the last 3,250 a. Nitrate fluctuations show seasonal, 11 and 22 a periodicities, and fluctuations show seasonal, 11 and 22 a periodicities, and fluctuations show seasonal, 11 and 22 a periodicities, and fluctuations show seasonal, 11 and 22 a periodicities, and solar activity peaks. Long-term lows and highs conform to solar activity minima and maxima. The data svailable support the hypothesis that nitrate is fixed in the upper atmosphere by some solar-mediated phenomenon causing a periodicity in East Antarctics snow. Background levels and non-periodic spikes in nitrate come from other sources. (Auth.) (Auth.)

EMATICS), EXPERIMENTATION.

Experimental and theoretical studies were made of the deformation and time-dependent failure of ice. Uniaxial compression tests were performed in the laboratory at constant and steadily increasing stresses. Strength criteries and unified constitutive equations describing all three stages of creep at constant stress are presented. It is shown that regardless of the stress regime (constant stress or step loading) the equations describe deformation and time-dependent failure by five parameters. The form of the constitutive equations, which can be applied also to describe the mechanical properties of frozen and unfrozen soils, make it possible to obtain analytical solutions of the practical problems and to determine

the creep parameters of frozen and unfrozen soils and ice in situ.

ICE CONTROL, RIVER ICE, LAKE ICE, THERMAL REGIME, HEAT TRANSFER, WATER FLOW, WATER TEMPERATURE, BUBBLING, ICE FORMATION, ICE GROWTH, ICE MELT-

ING, ANALYSIS (MATHEMATICS).

The thermal control of ice in rivers and lakes is accomplished in most cases by modifying the energy budget of the ice cover. In most cases the modification is to increase the flow of heat to the underside of the ice cover, either by directing against it a flow of warm water obtained from other parts of the water body, as in the case of air bubbler systems, or by increasing the temperature of the existing flow of water, as in the case of rivers.

IN-SITU MEASUREMENTS OF THE ME-CHANICAL PROPERTIES OF ICE. Tatinclaux, J.C., International Conference on Marine

Research, Ship Technology and Ocean Engineering, Hamburg, Sep. 29-30, 1982. Proceedings. Inter-maritec '82, Hamburg, 1982, p.326-334, 7 refs.

ICE MECHANICS, ICE COVER STRENGTH, ICE ELASTICITY, FLEXURAL STRENGTH, FLOATING ICE, ANALYSIS (MATHEMATICS).

Two methods for in-situ determination of the bending strength and elastic modulus of ice are presented. The first method and elastic modulus of ice are presented. The first method requires failure tests of a series of cantilever beams of various length over thickness ratios, while the second method is based on failure testing of a free-floating beam of length at least three times the ice characteristic length. Both methods avoid the need for measuring beam deflection in order to determine the elastic modulus. The analytical background of the methods is presented, and their advantages and disadvantages as compared to conventional methods are discussed together with their likely application to field or laboratory use.

STANDARDIZED TESTING METHODS FOR MEASURING MECHANICAL PROPERTIES OF

Schwarz, J., et al, Cold regions science and technology, July 1981, 4(3), p.245-254, 18 refs. Frederking, R., Gavrilo, V.P., Petrov, I.G., Hirayama, K., Mellor, M., Tryde, P., Vaudrey, K.D.

STANDARDS, LOADS (FORCES), TESTS.

The results of nominally similar tests vary greatly due to the fact that almost every ice research group uses different testing methods. This is of course a hindrance to the loc Engineering field. In order to improve the quality, comparability and usefulness of the test data resulting from mechanical property investigatious, the LAHR Section on Ice Problems considers it necessary to standardize ice testing methods. Herewith the Working Group of the LAHR Section on Ice Problems proposes its recommendation for "Standardized Testing Methods for Measuring Mechanical Properties of Ice." It should be noted that the suggested recommendations remain open to revision as the development of ice testing methods progresses.

FROST HEAVE, SOIL MECHANICS, SOIL FREEZING, ICE WATER INTERFACE, ICE SOLID INTERFACE, TESTS, CLASSIFICATIONS, TEMPERATURE GRADIENTS, SOIL WATER, PARTICLE SIZE DISTRIBUTION, GRAIN SIZE.

GRAIN SIZE.

Methods of determining the frost susceptibility of soils are identified and presented in this report. More than one hundred criteria were found, the most common based on particle size characteristics. These particle size criteria are frequently augmented by information such as grain size distribution, uniformity coefficients and Atterberg limits. Information on permeability, mineralogy and soil classification has also been used. More complex methods requiring pore size distribution, moisture-tension, hydraulic-conductivity, heave-streas, and frost-heave tests have also been proposed. However, none has proven to be the universal test for determining the frost susceptibility of soils. Based on this survey, four methods are proposed for further study. They are the U.S. Army Corps of Engineers Frost Susceptibility Classification System, the moisture-tension hydraulic-conductivity test, a new frost-heave test, and the CBR-after-thaw test.

DESIGNING WITH WOOD FOR A LIGHT-WEIGHT AIR-TRANSPORTABLE ARCTIC SHELTER: HOW THE MATERIALS WERE TESTED AND CHOSEN FOR DESIGN.

Planders, S.N., et al, Structural use of wood in adverse environments. Edited by R.W. Meyer and R.M. Kel-logg, New York, Van Nostrand Reinhold Co., 1982, p.385-397. Tobiasson, W.

37-1030 PORTABLE SHELTERS, WOODEN STRUCTURES, MILITARY TRANSPORTATION, COLD WEATHER TESTS, LOADS (FORCES), AIR-PLANES, DESIGN, CONSTRUCTION MATERI-

Construction of a prototype shelter particularly suited to accommodate a party of four to six in the extreme cold at remote locations has been completed recently. To facilitate transportation, the shelter doubles as an ISO shipping tate transportation, the shelter doubles as an ISO shipping container and self-loads onto military aircraft. These modes endure severe loads. Wood was chosen as a suitable material for use in the cold. The requirement for light weight necessitated that the wood be used close to its strength limits. The limits for bonding wood and employing composite panels were tested and compared with calculated values. Urethane-based adhesive was chosen to bound high-density overlay (HDO) plywood and redwood sections together. Fiberglass-reinforced plastic (FRF) mat was chosen as a material to strengthen webs against shear.

Data from anow lyaimeters in California and Vermont are used to find the saturated permeability of a melting snow cover in the range of 10-40x10/(10 ag m) depending on snow density. The unsaturated permeability increases as about the third power of liquid saturation. The gravity flow theory is shown to be an accurate representation of netwater drainage from snow covers in two diverse areas even though the snow covers are treated as homogeneous units. The variation of saturated permeability with unow density occurs about as predicted by Shimizu's formula for dry anow, although ice layers decrease the permeability somewhat.

37-1329 77-1329 FROST HEAVE, SOIL FREEZING, TRANSFER, MATHEMATICAL M MODELS, ANALYSIS (MATHEMATICS).

ANALYSIS (MATHEMATICS).

A unifying numerical method is developed for solution of frost heave in a vertical freezing column of soil. Within one general computer code a single unifying parameter can be preselected to employ the commonly used Galerkin finite elements, subdomain weighted residual, or finite difference methods as well as several other methods developed from the Alternation Theorem. Comparing results from the various numerical techniques in the computation of frost heave to measured frost heave in absoratory column indicates there is little advantage of the numerical technique over another.

(MATRISMATICS). From the theory of cantilever beams on an elastic foundation, it is shown that the atrength index and modulus index of ice can be determined from measurements of either the failure load or the tip deflection, or both, of in situ cantilever beams tested over a wide enough range of ratio of beam length to beam thickness. Four methods are proposed, two of which do not require the measurement of beam deflection during beam loading, an often difficult task to perform with sufficient reliability, especially in the field.

ELS.

For determining the characteristic length of a floating ice sheet, a vertical load is applied to the ice sheet either by placing dead weights in discrete increments or with a screw drive apparatus in series with a load cell, and the deflection of the ice sheet is monitored at the point of loading or near it. For a model ice sheet exhibiting creep behavior, the experimental results with the screw apparatus show that the slope of the load-deflection curve decreases as the load increases, and one is not able to choose a unique value of the slope for the computation of stress in ice.

This is attributed to relaxation of stress in ice.

BARTHQUAKES, VOLCANOES, FLUID DYNAMICS, FLUID FLOW, UNITED STATES—
OREGON—HOOD, MOUNT.

Low-frequency (<10 Hz) volcanic earthquakes originate at a wide range of depths and occur before, during, and after magmatic eruptions.

The characteristics of these earthquakes suggest that they are not typical tectonic events, country analogous processes occur in hydraulic fracturing of rock formations, low-frequency icequakes in temperate glaciers, and autoresonance in hydroelectric power stations. We propose that unsteady fluid flow in volcanic conduits is the common source mechanism of low-frequency volcanic arthquakes (tremor). The fluid dynamic source mechanism explains low-frequency earthquakes of arbitrary duration, magnitude, and depth of origin, as unsteady flow is independent of physical properties of the fluid and conduit. Fluid transients occur in both low-viscosity gases and high-viscosity dudids. A fluid transient analysis can be formulated as generally as is warranted by knowledge of the composition and physical properties of the fluid, material properties, geometry and roughness of the conduit, and boundary conditions. TIONS, ICE MODELS.

Some results from a series of three-year aperiodic simulations of the Northern Hemisphere sea ice cover are reported. The simulations employ the dynamic-thermodynamic sea see model developed by Hiber (1979) and use a one-day timestep on a 35 x 31 grid with a resolution of 222 km. Atmospheric data from the years 1973-75 are used to drive the simulationa. The simulations yield a seasonal cycle with excessive amounts of open water in the central Arctic during summer. Despite the seasonal bias, the simulated and observed interannual fluctuations are similar in magnitude and are positively correlated. The correlations with observed data are noticeably smaller when dynamical processes are omitted from the model. The simulated outflow of ice through the Greenland-Spitobergen passage undergoes large fluctuations both seasonally and on an interannual basis. The outflow correlates highly with the simulated fluctuations of ice coverage in the North Atlantic sector and positively with the observed fluctuations of ice coverage in the same sector.

MP 1580 ADHESION OF ICE TO POLYMERS AND OTHER SURFACES.

SIMPLE FIXED MESH FINITE ELEMENT SO-LUTION OF TWO-DIMENSIONAL PHASE CHANGE PROBLEMS.

O'Neill, K., International Offshore Mechanics and Arctic Engineering Symposium, 2nd, Houston, Texas, Jan. 30-Feb. 3, 1983. Proceedings. Edited by J.S. Chung and V.J. Lunardini, New York, N.Y., American Society of Mechanical Engineers, 1983, p.653-658, 24

37-2398 FREEZE THAW CYCLES, HEAT TRANSFER, PHASE TRANSFORMATIONS, LATENT HEAT, THERMAL CONDUCTIVITY, MATHEMATICAL MODBLS, ENTHALPY

An algorithm has been developed for two-dimensional freezing and thaving problems, which may also be useful for some other phase change problems. It is designed to be implemented simply in standard finite element best conduction computer codes which use linear interpolation within elements. Substances with discrete phase change temperatures such as water suffer a step change in enthalpy across a phase change isotherm, and hence feature a theoretically infinite heat capacity there. The algorithm handles this potentially troublesome phenomenon in a natural way through usual finite element procedures, using simple closed form expressions. MP 1585

ICE DYNAMICS IN THE CANADIAN AR-CHIPELAGO AND ADJACENT ARCTIC BASIN AS DETERMINED BY ERTS-1 OBSERVA-TIONS.

r, R.O., et al, Canada's continental margins and offshore petroleum exploration. Edited by C.J. Yorath, E.R. Parker and D.J. Glass, Calgary, Alberta, Canadian Society of Petroleum Geologists, May 1975, p.853-877, 13 refs. Campbell, W.J., Weeks, W.F., Drapier-Arsenault, L.,

ICE CREEP, ICE MECHANICS, STRESS STRAIN DIAGRAMS, LOADS (FORCES), COMPRESSIVE PROPERTIES, STATIC LOADS, TIME FACTOR, ANALYSIS (MATHEMATICS), TESTS, RHEOLO-

Results of mechanical tests involving uniaxial compression of isotropic ice at -5C were analysed and interpreted. Constant load (CL) creep tests were made for applied stresses in the range 0.8 to 3.8 MPa, and "strength" tests under constant displacement rate (CD) were made for applied strain rates in the range 1/10,000,000 to 1/1,000 1/a. Results from CL tests and CD tests corresponded closely, giving much the same information about failure strains, strength, creep rates, time to failure, stress/strain-rate relations, etc. MAP 1882 MP 1588

PHYSICS OF MATHEMATICAL FROST HEAVE

MODELS: A REVIEW.
O'Neill, K., Cold regions science and technology, Feb. 1983, 6(3), p.275-291, Refs. p.289-291. 37-2883

FROST HEAVE, FROZEN GROUND PHYSICS, THERMODYNAMICS, PHYSICAL PROPERTIES, STRESSES, MATHEMATICAL MODELS, GROUND ICE.

TROUND ICE.

This paper is concerned with the physical and thermodynamical bases of frost heave modeling. An attempt is made to isolate and illuminate issues which all such models must address, at least by implication. Although numerous relevant publications are surveyed, emphasis is less on an enumeration of items in the literature, and more on the concepts themselves, and on their alternative mathematical expressions, approximations, and manners of applications.

Ultimately a selection

of specific mathematical models is discussed, in light of the points raised in the general discussion.

NESS, STRESSES, ICE MODELS, PACK ICE. In large scale sea ice models ridging is modeled by redistributing thin ice into thicker categories. The way in which this redistribution is carried out can significantly affect the geophysical stresses in pack ice. This paper compares ice strength characteristics of several different redistributors and discusses the relationship of these redistributors with observed ridge morphological data. In addition, simulated Arctic Basin ridge buildup results using one of these redistributors are presented and compared to roughness observations reported in the literature.

Hibler, W.D., III, et al, Journal of geophysical research, Mar. 30, 1983, 88(C5), p.2873-2887, 29 refa. Ackley, S.F. 37-2983

SEA ICE, ICE MECHANICS, DRIFT, ICE MOD-ELS, ICE COVER THICKNESS, ANTARCTICA— WEDDELL SEA.

WEDDELL SEA.

The simulations employ a dynamic thermodynamic model developed in 1979 and use a 1-day time step on an 18 z 15 grid with a resolution of 122 km. Daily atmospheric data from 1979 are used to drive the simulations, which yield a seasonal cycle of ice with maximum extents close to that observed. The advance of the ice is primarily thermodynamic in nature, while the rapid decay depends critically on the presence of both leads and lateral ice advection. The average fraction of open water is substantial and varies from 10% in September to 35% in March. These values are in general agreement with estimates from satellite microwave data. Mean ice thicknesses are consistent with observations and vary from about 3 m in the perennal ice in the western Weddell. Simulated ice drift results yield mean drift rates of about 5 km/day, in good agreement with body drift observations with alightly inadequate northward transport in the western Weddell. Near the ice edge the drift rates are relatively insensitive to the ice strength. Near the coast, however, lower strengths are found to yield a decrease in northward drift rates. (Auth. mod.)

EMATICS).

The conduction problem for cylinders embedded in a medium with variable thermal properties cannot be solved exactly if phase change occurs. New, approximate solutions have been found using the quasi-steady method. These solutions consider heat flow from the entire pipe surface, rather than from a single point, as has been assumed in the past. The temperature field, phase change location, and pipe surface heat transfer can be evaluated using graphs presented for parametric range of temperature, thermal properties, burial depth, and insulation thickness.

Phase change phenomena arise frequently in applications such as thermal design in permafrost regions, thermal storage of latent heat for solar systems, and the heat treatment of metals. These are problems of conductive heat transfer with solidification phase change. Exact solutions are sought for geometries and boundary conditions which are simple and yet representative of practical systems.

FREEZE THAW CYCLES, PERMAPROST THER-MAL PROPERTIES, HEAT BALANCE, STEFAN PROBLEM, SOIL FREEZING, GROUND THAW-ING, LATENT HEAT, SURFACE PROPERTIES, HEAT TRANSFER, PHASE TRANSFORMA-TIONS, CONVECTION, ANALYSIS (MATH-EMATICS)

The study of conductive heat transfer with phase change—often called the Stefan problem—includes some of the most intractable mathematical areas of heat transfer. Exact solutions are extremely limited and approximate methods are widely used. This paper discusses the heat balance integral approximation using the collocation method. The method is applied to some standard problems of phase change—Neumann's problem—and a new solution is presented for the case of a semi-infinite body with surface convection. Numerical results are given for soil systems and also for materials of interest in latent heat thermal storage.

TEMPERATURE EFFECTS, ANALYSIS (MATH-EMATICS), THEORIES.

The growth of ice particles in dry seasonal snow is caused by vapor diffusion among particles due to temperature gradients imposed on the snow cover. The diffusion is calculated by using the potential field solutions for electrostatically charged particles. The stereography of snow is represented by using a log-normal distribution function for a geometric enhancement factor defined here. Reasonable crystal growth rates and supersaturations are found.

RONMENTAL PROTECTION, DESIGN.

New design curves for ice blasting relate crater radius with charge weight, charge depth, and ice thickness. Single-charge data can be used to design charge patterns for breaking ice in long channels or over broad areas. When charges are optimized to give maximum energetic efficiency, the specific energy is comparable to that for an ice-breaking ahip, and significantly lower than the best attainable specific energy for ice-cutting machines.

Shock attenuation curves for underwater explosions permit the calculation of safe distances for structures, fish and divers.

ICE FORCES ON MODEL MARINE STRUC-

Haynes, F.D., et al, International Conference on Port and Ocean Engineering under Arctic conditions, 7th, Helsinki, Finland, April 5-9, 1983. Proceedings, Espoo, Finland, Valtion teknillinen tutkimuskeakus, 1983, p.778-787, 7 refs. Sodhi, D.S. 37-3776

ICE PRESSURE, OFFSHORE STRUCTURES, ICE SOLID INTERFACE, FLEXURAL STRENGTH, ICE COVER THICKNESS, ICE COVER STRENGTH, ICE ELASTICITY, VELOCITY, EXPERIMENTATION.

PERIMENTATION.

Small-scale laboratory experiments were conducted on model marine structures in the CRREL test basin. The experiments were performed by pushing model ice sheets against structures and monitoring the ice forces during the ice-structure intersection. The parameters, varied during the test program, were the geometry of the marine structure and the velocity, thickness, and flexural strength of the ice. The results are presented in the form of ice forces on sloping and vertical structures with different geometries.

37-3962 PACK ICE, ICE CONDITIONS, SEA ICE DISTRI-BUTION, WEDDELL SEA.

BUTION, WEDDELL SRA.
Observations of pack ice in the Weddell Sea during the Weddell Polynya expedition (WEPOLEX-81) culminated in a daily map of ice conditions and a narrative observation log. The narrative log contains information on ice concentration, ridging, amounts of thin ice and open water, and unusual ice features. On the basis of observations, the pack ice zone has been divided into three regions ice edge region (within 0 to 60 naut. mi. of the northern limit of pack ice); ice edge-pack ice transition zone (within 60 to 160 naut. mi. of the outer limit of pack ice); and deep pack (at distances greater than 160 naut. mi. from the outer limit). In most satellite microwave images the ice edge-pack ice transition zone eppears as an area of lesser concentration. Observations did not confirm this. Also unexpected was the observation that noticeable swell propagation occurred at great distances from the outer pack limit.

SEA ICE. ICE COMPOSITION, ICE STRUCTURE, ALGAE, WEDDELL SEA

ALGAB, WEDDELL SEA.

Twenty of 27 ice cores and 13 surface ice samples taken between 59 deg 21 min S and 62 deg S have been analyzed for ice structure, salinity, nutrients, fluorescence, chlorophyll a, phaeo-pigment, diatom species enumeration, and becteria. The primary physical feature is the dominance of frazil ice structure as opposed to congelation ice. The salinity range is 2.4 to 13.7% with the higher salinities within the upper 15 cm. Chemical sualysis of nutrients in the cores indicates that they do not follow a dilution curve. Silicate, phosphate, and nitrate are found in higher concentrations in the adjacent surface than in the adjacent surface water. Evels, however, are two to five times higher in the surface layer of the ice cores than in the adjacent surface water. Chlorophyll a followed a pattern similar to that of nitrite. Phaeo-pigment ranged from 0.04 to 4.02 mg/cu m. Meltwater fluorescence appears to acale with salinity. Diatoms are present at all sample levels in the ice cores, but in varying concentration and condition. Active growth occurs in the surface layers.

FORMATION, COMPRESSED AIR.

Experiments have been performed under controlled and free environment conditions to determine the technical feasibility of using the cooling resulting from the adiabatic expansion of compressed air to initiate ice crystal production in a supercooled fog. These experiments have shown that for most supercooled temperatures, approximately 1000 cc of ir when compressed to 60 paig and released through a supersonic nozzle will produce the same number of ice crystals as does the evaporation of 1 cc of liquid propane. It is estimated that a compressed air supercooled fog dispersal system would consume approximately 6% of the hydrocarbon fuel presently consumed by operational systems using liquid propane spray.

CURRENTS, REMOTE SENSING.

Results of impulse radar studies of sea ice near Prudhoe Bay, Alaska, show that where there is a preferred current direction under the ice cover the crystal structure of the ice becomes highly ordered. This includes a crystal structure with a preferred horizontal c-axis that is oriented parallel with the local current. The radar studies show that this structure behaves as an anisotropic dielectric. The result is that when electromagnetic energy is radiated from a dipole antenna in which the E-field is oriented perpendicular with the c-axis azimuth, no bottom reflection is detected. It was also found that the frequency dispersion of anisotropic sea ice varies in the horizontal plane and is related to the average bulk brine volume of the ice. The bulk dielectric constant of the ice, as determined from impulse travel time, shows little correlation with the coefficient of anisotropy.

TION.

A cooperative ice core drilling, core processing, and stratigraphic logging program was conducted at Amundsen-Scott Station during the 1981-82 season by investigators from the Polar Ice Coring Office (PICO), the National Hydrology Research Institute Buvironment Canada (NHRR), and the U.S. Army Cold Regions Research and Engineering Laboratory (CRREL). A 202.4-m ice core was collected, logged and packaged in the field, and then shipped to the CRREL ice core storage facility, where it will be made available to the NSF sponsored gisciologists for further analysis. In addition to work with the ice core, PICO team members collected three gas samples for the Physics Inst., Univ. of Bern, Switzerland and prepared the Gearhardt-Owen logging winch for use by Univ. of Wisconsin-Madison geophysicists in their sonic logging of the 900-m borehole at Dome C.

MP 1622 CONTINUUM SEA ICE MODEL FOR A GLO-BAL CLIMATE MODEL.

SEA.

The model developed by Campbell (1965) has been extended to a time-dependent, quasi-steady-state model that uses both the equation of continuity and the equation of momentum. It also incorporates an equation of state that relates the pressure of ice to its convergence. The constitutive equation is of a fluid type. The freezing and melting of sea ice is parameterized in terms of ice thickness, location, and season. For the 1974 sustral winter twice-daily surface wind stress fields were generated from synoptic pressure data. For every third day of this period the boundaries and concentration of the Antarctic sea ice were mapped using ESMR (Electronically Scanning Microwave Radiometer) images acquired by the Nimbus-5 satellite. These data are used both as initial conditions and to compare the model results for various time periods.

REVIEW OF ELECTRICAL RESISTIVITY OF FROZEN GROUND AND SOME ELECTROMAGNETIC METHODS FOR ITS MEASURE-MENT.

Results of extensive studies of earth resistivities of low temps ture soils are presented. Ground measurements of telectromagnetic field components of radio waves propagat at low frequencies from distant transmitters and of the induction at low frequencies from distant transmitters and of the inductive coupling between two loop antennas are described. Results of measurements by these methods are compared with each other and with actual findings from excavations and borings at permatrost sizes. The measurements are abown to provide data on locations of lens ice, indicate zones of thawing give indications which permit estimating resistivities of layers and permit construction of a map of Alaska identifying major resistivity zones. Airborne evaluation of remotely propagated waves permits construction of resistivity contour maps. Reasons for variations in resistivity among various categories of frozen soils are discussed.

MODELS.

Due to the nonlinear nature of the ice interaction, sessioe build-up against coasts and structures is a complex process. This build-up significantly affects mesoscale (10 to 100 km) ice motions over typical forecast time scales of several days. To examine the ramifications of assuming a non-linear ice interaction in ice forecast models, we have carried out a series of idealized simulations employing a viscous plastic seas-ice rheology. These simulations employ constant wind fields at a grid resolution of 12.5 km and allow the ice to build up and strengthen.

With the plastic ice interaction the ice build-up is found to take place by means of a ridging front.

Depending on the nature of the strength-

thickness coupling, this build-up is accompanied by kinen wave propagation effects.

not push up and non-up are common occurrences along beaches in the sub-Arctic and Arctic. An understanding of the factors which lead to pile-up is important for design of a defensive strategy to prevent damage to coastal installations. Since ice action on a aloping beach is complex, an experimental model study was undertaken to determine the factors which promote ice pile-up. The factors varied in this study were the freeboard, slope, and roughness of the beach. One experiment was performed to observe the effectiveness of a shore defense structure against ice ride-up.

ROOFS, MOISTURE DETECTION, INFRARED RECONNAISSANCE, MEASURING INSTRU-MENTS

MBNTS.

Moisture is the big enemy of compact roofing systems. Nondestructive nuclear, capacitance and infrared methods can
all find wet insulation in such roofs but a few core samples
are needed for verification. Nuclear and capacitance surveys
generate quantitative results at grid points but examine only
a small portion of the roof. Quantitative results are not
usually provided by infrared scanners but they can rapidly
examine every square inch of the roof. Being able to
find wet areas when they are small is an important advantage. MP 1629

An experiment is described that demonstrates the balance between the ice and the unfrozen water in a frozen soil as water is removed. Nuclear magnetic resonance (NMR) is used to monitor the unfrozen water content as the soil is dehydrated by a molecular sieve material. Our results show that the unfrozen water content of a Morin clay soil remains constant until the total water content has been reduced to the point where no ice remains in the system.

ADHESION, COUTERMEASURES, TESTS.
Much effort over many years has gone into the search
for an effective, durable, easily applied and inexpensive material
to eliminate the force of adhesion between ice and a substrate.
The objective of zero ice adhesion on an unheated surface
which would either prevent the formation of ice or ensure
self-shedding of very thin accretions has not yet been achieved.
Many commercially-available coexities do succeed in reducing
the force of adhesion below 15 psi (1034 kPs) and survive
at least five freeze-release cycles, two arbitrarily established
criteria. Exposure to rain erosion, however, increases the
force of adhesion beyond this value for most materials.
As part of a continuing project at CREEL, a test procedure
for measuring the shear strength of ice at failure has been
developed and a large number of candidate materials have
been tested.

ICE LOADS, ICE PRESSURE, OFFSHORE STRUCTURES, IMPACT STRENGTH, ICE STRENGTH, RIVER ICE, LAKE ICE, ICE MECHANICS, STRAINS, TIME FACTOR, MEASUR-ING INSTRUMENTS.

ING INSTRUMENTS.

Methodologies and techniques are discussed for measuring ice forces on fixed structures situated in rivers and lakes. The usual method of measuring ice forces is to place a load frame between the moving ice and the structure and to measure the reactive forces with load cells or strain gages. Another method is to measure the acceleration, displacement or strain at a few points on the test structure and relate the measurements to ice forces. The size and shape of the force measuring system depend upon the mode of ice failure, the distribution of the ice forces and the logistics associated with each site. The variations of ice force with respect to time are generally very high during crushing and impact, and the response of the force-measuring system should be sufficiently fast.

FIFES (TUBES).

Ice action on two cylindrical structures, located side by side, has been investigated in a small-scale experimental study to determine the interference effects on the ice forces generated during loc structure interaction. The proximity of the two structures changes the mode of ice finhure, the magnitude and direction of ice forces on the individual structure, and the dominant frequency of ice force variations. Interference effects were determined by comparing the experimental results of tests at different structure spacings.

PUTER APPLICATIONS.

The equilibrium ice jam thickness given by Pariset et al, is modified to yield a clearer, consistent relationship between the flow hydraulics and thickness. The modified equations are analyzed with respect to a floating ice jam in the main channel with flow also occurring in the floodplain. The final derivation allows the expected ice jam thickness to be computed, given the bed and ice cover thickness. The analytical computation for the ice jam thicknesses is compared with prototype data on ice jam thicknesses from four shallow rivers which had significant floodplain flow with the ice iam event.

ASYMMETRIC PLANE FLOW WITH APPLICA-TION TO ICE JAMS.

JOSTON STREET STATES THE STEAR STRESS, FRICTION, SURFACE ROUGHNESS, VELOCITY, ANALYSIS (MATHEMATICS), TURBULENT FLOW.

BULENT FLOW.

An available turbulence method is used to prove that in plane flows between two boundaries with asymmetric roughness the plane of maximum velocity is not the plane of zero shear stress. By dividing the flow at the plane of zero shear stress, laboratory and field data on flows below simulated and actual ice jams are analyzed to derive equations for the boundaries triction factors in terms of mean flow velocity, depth of flow zone, and boundary roughness for smooth and fully rough boundaries. These equations are applied to the calculations of ice jam characteristics. For the jams studied, the present method gives a variation of about 10% in the jam characteristics with a method based on dividing the flow at the plane of maximum velocity.

SNOWFALL, MEASURING INSTRUMENTS, PRECIPITATION GAGES, VELOCITY, ELECTROMAGNETIC PROPERTIES, ANALYSIS (MATHEMATICS).

(MATHEMATICS).
A system has been developed by the U.S. Army Cold Regions Research and Engineering Laboratory to measure the mass concentration of falling anow crystals. It is known as ASCME (Airborne Snow Concentration Measuring Equipment) and is described in this paper.

ASCME's general performance has been evaluated based on concurrent measurements of precipitation rate.

A strong correlation between airborne-snow mass concentration and precipitation rate yields an estimate of particle full velocity close to that observed by other researchers.

Factors affecting system accuracy have been investigated and are discussed.

Examples are given of the utilization of ASCME data in analyses of electromagnetic energy propagation in falling anow. (Author) agnetic energy propagation in falling anow.

MP 1648 CHARACTERIZATION OF SNOW FOR EVALUATION OF ITS EFFECT ON ELECTRO-MAGNETIC WAVE PROPAGATION.

PROPAGATION, FREEZE THAW CYCLES.

Providing ground truth for the backscatter and absorption effects of a snow cover on electromagnetic waves has long seen a problem. One characteristic of the snow cover which has been particularly difficult to measure is its free, or liquid, water content—the fraction of the snow's volume which exists in the liquid state. Five methods which have been used for measuring this parameter are described and their merits and deficiencies are discussed. Two of the methods are calorimetric, measuring the free water content as a function of the heat added to or removed from a snow sample while completely melting or freezing it. The third uses the treezing point depression observed on adding a salt solution to a snow sample to calculate the snow's free water content. In the fourth procedure, a snow sample is completely dissolved in ethyl or methyl alcohol. The corresponding decrease in temperature is inversely related to the free water content of the snow. The final technique is electronic: above a certain frequency, the electrical capacitance of snow is related to its density and free water content. With accurate calibration, devices which measure snow capacitance are likely to be the simplest and fastest means of providing free water measurements. (Auth.)

MP 1650 COMMENTS ON THE METAMORPHISM OF SNOW.

Colbeck, S.C., Society of Photo-Optical Instrumenta-tion Engineers. Proceedings, 1983, Vol.414, p.149-151

38-1051

METAMORPHISM (SNOW), SNOWFALL, SNOW CRYSTAL GROWTH, GRAIN SIZE, TEMPERA-TURE GRADIENTS, CLIMATIC FACTORS, WET

SNOW.

Snow precipitation takes a variety of forms depending on the conditions in the atmosphere at the time of the snowfall. Regardless of what particular conditions prevail at that time, once the snow particles reach the ground they immediately begin changing. This is not surprising since the snow cover is at or close to its melting temperature, has a very conditions.

Wet snow and dry snow are very different atterials. They have different properties and even looked different. They have different properties and even looked different. They snow the different properties and even looked different they begin the processes. They are treated separately here. Dry snow is treated first because dry snowfall followed some time later by melting is the normal sequence of events. (Auth.)

SAT, CLOUD COVER, MAPPING.

The TM aboard Landsat-4 launched on July 16, 1982, represents a major advance in Barth resources sensors. Its seven spectral bands record surface radiation in blue, green, red, near infrared, middle infrared and thermal wavelengths. The spatial resolution of approximately 30 meters represents a sevenfold increase over the previous Landsat sensor, the multispectral scanner subsystem (MSS). In addition, TM has greater radiometric sensitivity, distinguishing 256 quantization levels, compared with 64 for the MSS. These potential improvements have significant implications for satellite remote sensing in cold environments. The addition of the middle infrared bands will permit clouds to be distinguished from snow. It may also be possible to relate spectral response in this range to snow condition and hence water content. The thermal band responds to differences in surface temperature, which may be related to variations in soil moisture and drainage. These are important considerations for cold region construction. (Auth.)

EFFECT OF COLOR AND TEXTURE ON THE SURFACE TEMPERATURE OF ASPHALT CON-CRETE PAVEMENTS.

Berg, R.L., et al, International Conference on Permafrost, 4th, Fairbanks, Alaska, July 17-22, 1983. Proceedings, Washington, D.C., National Academy Press, 1983, p.57-61, 11 refs.

ALASKA—SUKAKPAK MOUNTAINS.
Several hundred mounds occur on the lower slope of Sukakpak
Mountain. The mean mound height is approximately 1
m and most are elliptical or circular in plan. Clear, massive
ice can be found within, below, and adjacent to some mounds.
Within and adjacent to one mound, free water under low
pressure was observed in late winter. Prozen sediments
were found below the water lens. Prozen sediments
were found below the water lens. Prozen sediments
curvature on top of the mounds suggest long period
of stability. Most mounds are found in active drainage
channels that develop thick surface icings each winter. As
a tentative hypothesis, it is suggested that the mounds form
by closed-system freezing at sites with higher moisture contents
than their aurroundings. The causes and frequency of
occurrence and annual magnitude of this upheaving are under
investigation.

STREAM FLOW, WATERSHEDS, DISCONTINUOUS PERMAPROST, SNOWMELT, PRECIPITATION (METEOROLOGY), MOSSES, SLOPES,
EVAPOTRANSPIRATION.

EVAPOTRANSPIRATION.

Precipitation-runoff ratios were measured on Glenn Creek, as mall, second-order, subarctic stream located near Fairbanka, Alaska, in the Yukon, Tanana Upland physiographic province. Glenn Creek drains a watershed of 2.25 sq km, of which 70% is underlain by permafrost.

A Paraball flume was used to measure streamflow, and a pair of 1.22 m by 2.44 m lysimeters were used to measure precipitation and runoff from the moss-covered permafrost alope. The data from one summer season (1979) and one snowmelt season (1980) indicate the aloping surfaces of the watershed have a very fast response time, long recession, and subsurface runoff prior to complete saturation of the overlying organic material. Glenn Creek streamflow is comparable to the lysimeter runoff with regard to response time and runoff recession, however the watershed precipitation-runoff ratio is much lower. This is attributed to longer travel distances in the watershed which result in greater evapotranspiration losses, little contribution from the non-permafrost areas, and only partial areas of the watershed contributing to the streamflow.

FROST HEAVE OF SALINE SOILS.

Chamberlain, E.J., International Conference on Permafrost, 4th, Fairbanks, Alaska, July 17-22, 1983. Proceedings, Washington, D.C., National Academy Press, 1983, p.121-126, 8 refs.

SALINE SOILS, FROST HEAVE, SOIL CHEMISTRY, SOIL FREEZING, ICE LENSES, BRINES, SHEAR STRESS, TESTS.

SHEAR SIRESS, IESIS.

Theories of ice segregation and frost heave processes in saline soils are briefly examined and modified to explain observations made on clay and sand soils frozen under laboratory conditions. Seawater was observed to reduce the rate of frost heave by more than 50% for both soil types and to dramatically reduce the size of ice lenses. The effect of seawater is to cause the formation of a thick active freezing zone with many ice lens growth sites, each with its own brine concentration. Unbounded brine-rich soil zones between ice lenses are identified as potential zones of low shear strength.

LONG-TERM ACTIVE LAYER EFFECTS OF CRUDE OIL SPILLED IN INTERIOR ALASKA. CRUDE UIL SPILLED IN INTERIOR ALASKA. Collins, C.M., International Conference on Permafrost, 4th, Fairbanks, Alaska, July 17-22, 1983. Proceedings, Washington, D.C., National Academy Press, 1983, p.175-179, 19 refs. 38-1131

OIL SPILLS, ACTIVE LAYER, ENVIRONMENTAL IMPACT, THAW DEPTH, ALBEDO, SEASONAL VARIATIONS, TEMPERATURE EFFECTS, UNITED STATES—ALASKA.

PBC18, UNITED STATES—ALASMA.

Two experimental oil spills of 7570 liters each were conducted at a black-spruce-forested site in February and July of 1976.

The long-term effects of the spills on the active layer were directly related to the method of oil movement. The winter spill moved beneath the snow, within the surface moss layer, and the summer spill moved primarily below the moss, in the organic soil. The summer spill affected an area nearly one and one-half times that of the winter spill. Only 10% of the 303 sq m summer spill area had oil visible on the surface, while 40% of the 188 sq m winter spill had visible oil. Thew depths in the summer spill area increased from 1971 to 1980—average thaw depth was 72 cm vs. 48 cm in the control—and remained essentially the same in 1981 and 1982. Thew depths in the winter spill area consistently higher than under the blackened surface. Presumably the change in albedo due to the surface oil accounts for the increased thaw in the winter spill area. spill area

MODELS, ICE LENSES, ICE MELTING.

A one-dimensional mathematical model of frost heave based upon a nodal domain integration analog is compared to data collected from a Winchendon, Mass, field site. Air and soil temperatures, pore water pressures, and groundwater level data were collected on test sections containing aix different soils during the winters of 1978-1979 and 1979-1980. The soil samples were evaluated in the laboratory to determine soil moisture characteristics, hydraulic conductivity as a function of pore water tensions, density, and other parameters. The parameters were used together with assumed thermal parameters in a one-dimensional model that calculates the distributions of temperature and moisture content as well as the amount of ice segregation (vertically lumped frost heave) and thaw consolidation. Using measured air and soil surface temperatures as input data, the simulated frost heave and thaw consolidation agreed well with measured and soil surface temperatures as input data, the simulated frost beave and thaw consolidation agreed well with measured ground surface displacements that resulted from ice segregation or ice lens melting.

TEMPERATURE, UNITED STATES—ALASKA.

TEMPERATURE, UNITED STATES—ALASKA.

Mean annual air temperatures (MAAT) are estimated for
transact from central to northern Alaska. The estimated
MAAT are compared to mean annual ground temperatures
(MAGT) representative of upper permafrost temperatures.
The estimation of MAAT for the remote and topographically
complex transact area was based on trend surface estimates
of numerous short-term (1-7 years) temperature records for
numerous short-term (1-7 years) temperature records from
and longer records from existing National Weather Service
stations. The standard error of the estimated MAAT
falls within a degree (C) of observed MAAT for stations
with long-term records. The MAGT are based on subsurface
thermistor measurements made at construction sites and are
therefore from disturbed terrain, but data were selected to
minimize the effects of disturbance.

MAGT measurements
ranged from -1.5 C, in the north to -0.7 C near Fairbanks.

Predicted MAAT ranged from -11.5 C at Prudhoe Bay
to -4.5 C in the Pairbanks area.

The time- and position-dependent locations of the 0 C isotherm were calculated using two modelling strategies: a domain

method and a boundary integral method. Simulations were made for the runway embankment at Deadhone Airport near Prudhoe Bay, Alaska. The same thermal properties, initial conditions, and boundary conditions were used in both models. Sinusoidal surface temperature variations, dependent upon surface type and exposure, were used in the simulations rather than measured surface temperatures. The positions of the 0 C isotherm determined by the boundary integral method near the time of maximum thaw penetration were essentially the same as those determined by the finite element method, and results from both models agreed closely, within a few centimeters over a total freezing depth of about 2.5 m, with the measured positions. The largest differences between measured and computed positions occurred early in the freezing and thawing seasons. The primary advantage of using the boundary integral method for problems specifically of the type considered herein is that it requires only a few modal points, so computer simulations can be completed rapidly on a micro computer. If the two-dimensional thermal regime is necessary, the finite element method is most suitable. method is most suitable

MP 1660 RECOVERY AND ACTIVE LAYER CHANGES FOLLOWING A TUNDRA FIRE IN NORTH-WESTERN ALASKA.

THE REPORT OF THE PROPERTY OF

38-1108

TUNDRA, FIRES, REVEGETATION, PERMA-FROST, ACTIVE LAYER, THAW DEPTH, GROUND ICE, HUMMOCKS, SOIL TEMPERA-TURE.

TURE.

An upland tundra fire, started by lightning, burned 48 sq km near the Kokolik River in northwestern Alaska during late July and early August 1977. Permanent plots were established to monitor recovery of severely, moderately, and tightly burned areas as well as unburned tundra. During the following 5 years the original permanent plots and other portions of the burn were observed annually. Vegetative recovery was most rapid and active layer effects were least on a high-centered polygonal area and on severely burned tussock tundra. By August 1979 the sedge-shrub vegetation had largely recovered while both the polygonal ground and the tussock tundra were still readily recognizable as burned areas. Accelerated hydraulic and thermal erosion had occurred on some slopes, resulting in exposures of massive bodies of ground ice. Active layer thicknesses averaged 27 cm in the unburned areas and 35 cm within severely burned areas in August 1977 and reached a maximum at all but one site in August 1979. Depth of thaw decreased between 1979 and 1982 in the sedge-shrub tundra and in the lightly burned shrub tundra and remained at the same increased level through 1982 at all other sites.

CYCLES, AERIAL SURVEYS.

The distribution and volume of ice in perennially frozen sediments beneath three unglaciated sites in northern Alaska vary with the grain size and depositional origins of the sediment, thermal history (permafrost aggradation and degradation), and age of the terrain and deposits. Substantial lateral variation in near-surface ice volume exists between and within each site, but reasonably consistent trends in ice content with depth were measured beneath individual landforms. Primary deposits, those deposited and frozen without postdepositional thermal or sedimentologic modification, contain the highest volume of ice at each locality. Sediments that have undergone thawing or resedimentation typically contain much less access ice. Thaw lake, slope, or fluvial processes modify ice contents and produce sedimenor fluvial processes modify ice contents and produce sedimen-tary sequences with a spatial distribution of ice determined by these depositional processes and the subsequent thermal history.

TABLE, TESTS.
Studies have indicated a relation between subfreezing temperature in a fine-grained soil and pressure (moisture tension) in the film water adjacent to an ice lens. During the experiments reported here, concurrent measurements were obtained of temperature and pressure in the liquid water phase of a freezing silt soil. Preezing was from the top down utilizing an open system, with the water table held at the base of a specimen 30 cm long. The freezing front advanced into the specimen at a generally decreasing rate from 20 mm/day to 5 mm/day. The tests utilized a special tensioneter developed at CRREL that continues to measure moisture tension below a temperature of 0 C as long as continuity with the unfrozen water is maintained. Moisture tensions were registered continuously up to 75 kPa (0.75 atm), after which the tension remained constant or decreased slightly.

SOIL-WATER DIFFUSIVITY OF UNSATURATED FROZEN SOILS AT SUBZERO TEMPERA-

Nakano, Y., et al, International Conference on Perma-frost, 4th, Pairbanks, Alaska, July 17-22, 1983. Pro-ceedings, Washington, D.C., National Academy Press, 1983, p.889-893, 26 refs. Tice, A.R., Oliphant, J.L., Jenkins, T.F. 38-1260

UNFROZEN WATER CONTENT, SOIL WATER, DIFFUSION, WATER TRANSPORT, TEMPERATURE EFFECTS, WATER CONTENT, GROUND

ICE.

The soil-water diffusivities of soils containing no ice were determined at -1 C by an experimental method recently introduced. The theoretical basis of the method is presented. The measured diffusivities of three kinds of soils are found to have a common feature in that the diffusivity increases with increasing water content, attains a peak, and increases again as the water content increases. This common feature of the soils at the subzero temperature is discussed in comparison with unfrozen soils. The experimental data appear to indicate that the basic transport mechanism of water in soils containing no ice at the subzero temperature is essentially the same as that in unfrozen soils containing a small amount of water.

The distribution of high-velocity material was used as an indicator of ice-bonded permafrost. Observations from ice survey and marine seismic records, coupled with control from a small number of drill holes, suggest that ice-bonded permafrost is extremely widespread in the Beaufort Sea. Large areas of high-velocity material at shallow depths, 10-40 m below the seabed, were observed near Prudhoe and Harrison Baya. In some cases these zones extended up to 35 km from shore. It was also common to find that depths to the high-velocity material increased with distance from the shore. Observed depths were as great as 150-230 m below the seabed.

MP 1666 WATER MIGRATION DUE TO A TEMPERA-TURE GRADIENT IN FROZEN SOIL

Oliphant, J.L., et al., International Conference on Permafrost, 4th, Fairbanks, Alaska, July 17-22, 1983. Proceedings, Washington, D.C., National Academy Preas, 1983, p.951-955, 10 refs. Tice, A.R., Nakano, Y.

PERMAPROST HYDROLOGY, FROZEN GROUND PHYSICS, SOIL WATER MIGRATION UNPROZEN WATER CONTENT, BOUNDARY **FROZEN** TEMPERATURE GRADIENTS, EX-PERIMENTATION.

Closed soil columns at an initially uniform total water content were subjected to a nearly linear and constant temperature gradient along their length. At various times, the columns were sectioned and water content as a function of position was determined gravimetrically. Unfrozen water content was temperature curves were also determined with a nuclear magnetic resonance technique on separate samples of the aame soil at the same dry density. It was found that the water migrated from the warm to the cold end and two zones developed in each of the tubes, one that contained only liquid water and the other containing ice and water. The boundary between the two zones also migrated toward the cold end as the experiment progressed, and the water content of the zone containing only water fell while that of the zone containing ice and water increased. were subjected to a nearly linear and constant temperature gradient along their length. At various times, the columns

ATMOSPHERIC BOUNDARY-LAYER MODIFI-CATION, DRAG COEFFICIENT, AND SURFACE HEAT FLUX IN THE ANTARCTIC MARGINAL ICE ZONE.

Andreas, E.L., et al, Journal of geophysical research, Jan. 20, 1984, 89(C1), p.649-661, 71 refs. Tucker, W.B., Ackley, S.F. 38-1819

BOUNDARY LAYER, METEOROLOGICAL IN-STRUMENTS, HEAT FLUX, ICE EDGE, RADI-OSONDES

OSONDES.

During a traverse of the Antarctic marginal ice zone (MIZ) near the Greenwich Meridian in October 1981, we launched a series of radiosondes along a 150-km track starting at the ice edge. Since the the wind was from the north, off the ocean, these radiosonde profiles showed profound modification of the atmospheric boundary layer (ABL), as the increasing surface roughness decelerated the flow. The primary manifestation of this modification was a lifting of the inversion layer with increasing distance from the ice edge by the induced vertical velocity. But there was also a cooling of the stably stratified mixed layer below the inversion and a consequent flux of sensible heat to the surface that averaged over 200 W/sq m. The magnitude of this flux suggests that atmospheric heat transport plays a significant role in the destruction of ice in the Antarctic MIZ. Using the rising of the inversion and ABL similarity theory, we estimated the neutral stability drag coefficient across the MIZ increased from its open ocean value, 0012, at the ice edge to 0.04 at 80-90% ice concentration. We present an equation for this dependence of drag on ice concentration that should be useful for modeling the surface stress in marginal ice zones. (Auth.)

MP 1668 ANTARCTIC SEA ICE MICROWAVE SIGNA-TURES AND THEIR CORRELATION WITH IN SITU ICE OBSERVATIONS.

Comiso, J.C., et al, *Journal of geophysical research*, Jan. 20, 1984, 89(C1), p.662-672, 24 refs. Ackley, S.F., Gordon, A.L. 38-1820

ICE SEA ICE DISTRIBUTION, MICROWAVES, REMOTE SENSING, SPACEBORNE PHOTOGRAPHY, ANTARCTICA—WEDDELL SEA.

The general characteristics and microwave radiative properties of sea ice in the Weddell Sea region during the onset of spring are studied by using the NIMBUS 7 Scanning Multichannel Microwave Radiometer (SMMR) and other satellite sensors in conjunction with in situ observations. The position of the ice edge, the gradient of ice concentration, and the width of the Marginal Ice Zone are inferred from the microwave width of the Marginal loe Zone are inferred from the microwave data and are found to be consistent with ship observations especially at 18 GHz. The sensitivities of the various SMMR frequencies to surface and other effects are investigated by using multi-spectral cluster analysis. The results show considerable variability in emissivity, especially at 37 GHz, likely associated with varying degrees of surface wetness. Ice concentrations are derived by using two methods: one that assumes fixed emissivities for consolidated ice and an iterative procedure that accounts for the variable emissivities to be variable gives ice concentrations that are more consistent with qualitative field observations. (Auth.)

MP 1669 POSSIBILITY OF ANOMALOUS RELAXATION DUE TO THE CHARGED DISLOCATION PROC

(FORCES), TEMPERATURE EFFECTS, ICE ACOUSTICS, RHEOLOGY, TESTS.

ACOUSTICS, RHEOLOGY, TESTS.

This work examines the effect of the rate of stress application on the creep behavior of polycrystalline ice. Stress rates from 1/1000 to 1.84 MPa/s were used to achieve a creep stress of 3.6 MPa at test temperatures of -5 and -10°C. The treatment emphasizes the effect of stress application rate on primary behavior and the accompanying microfracturing activity. Acoustic emission measurements taken in all tests indicate the onset and rate peak of the microfracturing activity. The stress application rate has little effect on the minimum strain rate, the strain at which it occurs, or the characteristics of tertiary creep provided that the loading ramp ends prior to reaching the nominal failure strain of 1.0 percent. Primary creep behavior is significantly affected only at rates below about 1/100 MPa/s. Results indicate that when the loading ramp continues through the failure strain, no minimum strain rate occurs, but rather the strain rate increases monotonically throughout the entire test.

TIONS, CLIMATE, ICE ACOUSTICS.

The marginal ice zones (MIZ) are regions where temperate and polar climate systems interact, resulting in strong horizontal and vertical gradients in the atmosphere and the occan. These gradients lead to mesoscale processes which affect the heat, salt, and momentum fluxes at the ice margin. It is therefore important to increase our understanding of these processes in order to model the air-ice-occan system in the MIZ, and to build up a predictive capability of the ice margin. Parameterization of these processes is also necessary in large scale modeling of the sea ice influence

on the global climate system. This paper reviews our knowledge of physical processes occurring in the marginal ice zones, points out problem areas and describes Marginal ice Zone Program (MIZEX) to be initiated in 1983.

ICE MECHANICS, SEA ICE, ICE LOADS, ICE-BERGS, ICE ISLANDS, ICE STRENGTH, STRESS STRAIN DIAGRAMS, ICE STRUCTURE, ICE COMPOSITION, SCANNING ELECTRON MICROSCOPY, ARCTIC OCEAN.

The mechanical properties are reviewed for the main types of ice in arctic seas glacial (icebergs), shelf (ice islands), sea ice; and representative values are given. Each ice type possesses a characteristic range of structures and compositions that differentiate it from other varieties of ice and to a considerable extent, these produce large variations in mechanical properties.

Factors affecting mechanical properties (temperature, brine and gas volume, crystal orientation and size, strain rate) are discussed, as are gaps, contradictions, and inadequacies in available data.

TRANSFER, ICE MELTING, ICE COVER STRENGTH, SOLAR RADIATION, ALBEDO, THERMAL REGIME.

THERMAL REGIME.

The deterioration of floating ice covers is analyzed to determine under what conditions the ice cover loses strength due to internal melting. The analysis considers the interaction between sensible heat transfer and long wave radiation loss at the surface, the surface albedo, the short wave radiation penetration and absorption and the unsteady heat conduction within the ice. The thermal analysis then leads to a determination of the porosity of the ice that allows strength analysis to be made using beam-type analyses. The results provide criteria to determine when and how rapidly the ice cover loses strength and under what conditions it will regain the original strength associated with an ice cover of full integrity.

PERFORMANCE OF A THERMOSYPHON WITH AN INCLINED EVAPORATOR AND VER-TICAL CONDENSER.

TEMPERATURE EFFECTS.

A two-dimensional model of coupled beat and moisture flow in frost-heaving soils is developed based upon well known equations of heat and moisture flow in soils. Numerical solution is by the nodal domain integration method which includes the integrated finite difference and the Galerkin finite element methods. Solution of the phase change process is approximated by an isothermal approach and phenomenological equations are assumed for processes occurring in freezing or thawing zones. The model has been verified against experimental one-dimensional freezing soil column data and experimental two-dimensional soil thawing lank data as well as two-dimensional soil acepage data. The model has been applied to several simple but useful field problems such as roadway embankment freezing and frost heaving.

MP 1679 SUMMARY OF THE STRENGTH AND MODU-LUS OF ICE SAMPLES FROM MULTI-YEAR PRESSURE RIDGES.

PUKI SEA.

Over two hundred unconfined compression tests were performed on vertical ice samples obtained from ten multiyear pressure ridges in the Beaufort Sea. The tests were
performed on a closed-loop electrohydraulic testing machine
at two strain rates (1/100,000 and 1/1000/s) and two temperatures (-20 and -5C). This paper summarizes the sample
preparation and testing techniques used in the investigation
and presents data on the compressive strength and initial
tangent modulus of the ice.

VARIATION OF ICE STRENGTH WITHIN AND BETWEEN MULTIYEAR PRESSURE RIDGES IN THE BEAUFORT SEA.

Weeks, W.F., International Offshore Mechanics and Arctic Engineering Symposium, 3rd, New Orleans, Louisiana, Feb. 12-17, 1984. Proceedings, Vol.3. Edited by V.J. Lunardini, New York, American Society of Mechanical Engineers, 1984, p.134-139, 6 refs. 38-2036

ICE STRENGTH, PRESSURE RIDGES, COM-PRESSIVE PROPERTIES, ICE STRUCTURE, ICE COVER STRENGTH, STRAINS, TEMPERATURE EFFECTS, POROSITY, SEA ICE, BEAUFORT

SEA.

A recent series of tests on the uniaxial compressive strength of ice samples taken from multiyear pressure ridges allows the testing of several hypotheses concerning the variation in strength within and between ridges. The data set consists of 218 strength tests performed at two temperatures (5 and -20C) and two strain rates (1/1000 and 1/100,000/s). There was no significant difference between the strength of the ice from the ridge sails and the ice from the ridge keels when tested under identical conditions. As the total porosity of the ice from the sails is higher by 40% than the ice from the keels, the lack of a significant difference is believed to result from the large variations in the structure of the ice which occur randomly throughout the cores. A three-level analysis of variance model was used to study the variations in strength between 10 different ridges, between cores located side by side in a given ridge, and between samples from the same core. In all cases the main factor contributing to the observed variance was the difference within cores. This is not surprising considering the rather extreme local variability in the structure of ice in such ridges. There was no reason at the 5% level of significance to doubt the hypothesis that the different cores at the same site and the different ridges have equal strength means.

RELATIONSHIP BETWEEN CREEP AND
STRENGTH BEHAVIOR OF ICE AT FAILURE. AND Cole, D.M., Cold regions science and technology, Oct. 1983, 8(2), p.189-197, 4 refs.

38-1513

ICE STRENGTH, ICE CREEP, ICE MECHANICS, STRESSES, STRAINS.

STRESSES, STRAINS.

This work explores the correspondence between the results of creep and strength tests performed on isotropic polycrystaline ice. A unique experimental procedure, termed a two-mode test in the present work, allows the testing of a single specimen under conditions of constant deformation rate up to failure and constant load thereafter. Using this procedure, the prevailing values of stress, strain and strain rate can be compared at the failure point under the two test modes without the influence of specimen variation. The effect of the stress path prior to failure on the creep behavior after failure can also be investigated. Results indicate coincidence of the failure points from creep and strength tests in stress/strain-rate/strain space. Furthermore, it appears that within the range of variables tested, the creep behavior after the mode switch at failure is independent of the stress path experienced before failure. (Auth.)

38-1495 PERMAFROST PERMAFROST BENEATH STRUCTURES, FOUNDATIONS, BUILDING CODES, SOIL CLASSIFICATION, SETTLEMENT (STRUCTUR-AL), SOIL CREEP, SAFETY.

AL), SUIL CREEF, SAFELY.

A comparative study was made of design criteria and analytical methods for footings and pile foundations on permafrost employed in U.S.S.R. Design Code SNiP II-8-76 (1977) and U.S. Army CRREL SR 80-34 developed in the early 1970s by the U.S. Army Corps of Engineers and published in 1980. The absence of adequate constitutive equations for frozen soils and of rigorous solutions of the boundary problems has made it necessary to incorporate (explicitly for inczen sous and or ingrous solutions of the boundary problems has made it necessary to incorporate (explicitly or implicitly) various safety factors in the foundation analyses. From the review it is concluded that the principal difference between these practices is in the assessment and application of appropriate values of safety factors, which leads to a substantial discrepancy in the dimensions and costs of footings and pile foundations in permafrost. ICE, LOADS (FORCES), POROSITY.

A series of 222 uniaxial constant-strain-rate compression tests were performed on vertical multi-year pressure ridge sea ice samples. A preliminary analysis of the effect of structure on the compressive strength of the ice was performed on 78 of these tests.

Test parameters included a temperature of -5C (23F) and strain rates of 1/100,000 and 1/1000/s. Columnar ice loaded parallel to the elongated crystal axes and perpendicular to the crystal c-axis was consistently the strongest type of ice. The strength of the columnar samples decreased significantly as the orientation of the elongated crystals approached the plane of maximum shear. Samples containing granular ice or a mixture of granular and columnar ice resulted in intermediate and low strength values. No clear relationship could be established between structure and strength for these ice types. However, in general, their strength decreased with an increase in porosity.

MP 1686 INPLUENCE OF GRAIN SIZE ON THE DUC-TILITY OF ICE.

Cole, D.M., International Offshore Mechanics and Arctic Engineering Symposium, 3rd, New Orleans, Louisiana, Feb. 12-17, 1984. Proceedings, Vol.3. Edited by V.J. Lunardini, New York, American Society of Mechanical Engineers, 1984, p.150-157, 21 refs. 38-2039

(FORCES), BRITTLENESS, TESTS.

(FORCES), BRITTLENESS, TESTS.

This paper presents observations made regarding the influence of grain size on the extent of internal cracking and creep behavior of polycrystalline ice. The test material was initially isotropic, laboratory prepared polycrystalline ice. Grain size ranged from 1.52 to 5.65 mm. Specimens were tested under constant load in uniaxial compression with an initial stress of 2MPa and at a temperature of -5C. Optical post-test analysis showed that the estimated crack density varied over nearly three orders of magnitude as the grain size increased by a factor of three. The smallest-grained specimen exhibited no visible fractures. The strain at the minimum creep rate decreased significantly as the grain size, and hence the fracturing activity increased. These observations indicate that under the prevailing test conditions, the stated variations in grain size alone can initiate the ductile-to-brittle transition. Discussion centers on a micro-mechanical explanation of the test results as well as the implications of the findings to areas of practical concern.

MP 1687 EXPERIMENTAL DETERMINATION OF BUCKLING LOADS OF CRACKED ICE SHEETS. FLOATING ICE, ICE CRACKS, ICE SHEETS, LOADS (FORCES), ICE SOLID INTERFACE, ICE LOADS, ICE DEFORMATION, EXPERIMENTA-

An experimental study was undertaken to determine the buckling loads of cracked, floating ice sheets. The configurations of the cracks considered in this study were symmetrical and unsymmetrical with respect to the structure and the direction of loading. The results of this study are compared with those of a theoretical study using a finite element method. The comparison between the two results is good although there is some scatter in the experimental data.

SNOW PARTICLE MORPHOLOGY IN THE SEASONAL SNOW COVER.
Colbeck, S.C., American Meteorological Society.
Bulletin, June 1983, 64(6), p.602-609, 14 refs.

38-2095 SNOWFLAKES, SNOW MORPHOLOGY, SNOW CRYSTAL STRUCTURE, SNOW WATER CON-TENT, SNOW COVER, FREEZE THAW CYCLES, PARTICLES, DEPTH HOAR, METEOROLOGI-

CAL FACTORS.

Snow precipitation degenerates rapidly once it reaches the ground. A wide variety of particle types develop in seasonal snow covers, thus leading to a wide range of snow properties. The most common varieties of particles are shown here. The physical processes responsible for the growth and development of these particles are described in general terms, althouth these processes are not understood as well as the processes of crystal growth in the atmosphere. The heat and mass flows associated with the development of these crystals in the snow cover are complicated because of snow's complex geometry.

MP 1689 USE OF RADIO FREQUENCY SENSOR FOR SNOW/SOIL MOISTURE WATER CONTENT MEASUREMENT.

McKim, H.L., et al, U.S. Army Cold Regions Research and Engineering Laboratory. Special report, Aug. 1983, SR 83-31, Snow symposium, 3rd, Hanover, NH, Aug. 9-10, 1983. Proceedings, Vol.1, p.33-42, ADB-079 265, 16 refs.

SNOW WATER CONTENT, SOIL WATER,
SNOW BLECTRICAL PROPERTIES, SOIL PHYSICS, UNFROZEN WATER CONTENT, MEASURING INSTRUMENTS, DIELECTRIC PROP-ERTIES, TESTS, TEMPERATURE EFFECTS.

A solid-state, durable, inexpensive radio frequency sensor (RFS) has been developed and laboratory-tested. The RFS uses a Wien bridge circuit to measure a change in soil impedance when changes in soil moisture occur. Both electrical conductance and capacitance are measured at differing moisture contents. The dielectric constant of the soil

moisture is proportional to the measured capacitance and is approximately linear with respect to percent moisture. Due to the simple readout system, the RFS has the potential to be interfaced to a data collection system for data acquisition from remote areas. Preliminary tests on the temperature effect of the RFS accuracy have shown that volumetric water content can be obtained by the RFS over a wide range of temperatures. In addition to the soil moisture measurement, preliminary tests on the measurement of the liquid water-content of snow have been made. Comparison of the results with the calorimetric method indicate that the RF sensor can be used to measure snow water content. Since the RFS is soild state, it can be placed in remote areas and can monitor volumetric soil water content to within 0.5% by volume.

COMPARATIVE NEAR-MILLIMETER WAVE PROPAGATION PROPERTIES OF SNOW OR RAIN.

RAIN.

SNOW WATER EQUIVALENT, REMOTE SENS-ING, HYDROLOGY, FORECASTING, LAND-SAT, SNOW DEPTH.

Messurements of anow depth and its water equivalent were obtained at 11 snow courses in the Allasash, Maine, area in conjunction with acquisition of five Landsat-2 and -3 images during the 1977-78 and 1978-79 winters. Digital imagery data acquired on 31 May 1978, when the land was snow-free, was used to classify land cover categories. Ground truth water equivalent measurements of snow were carea-weighted using the land cover classification to deriver earea-weighted using the land cover classification to deriver engional mean water equivalent values for snow cover on each of the five Landsat scenes. The 1 March 1978 snow measurement of 19.46 cm of water equivalent was used as an input value to the SSARR (Streamflow Synthesis and Reservoir Regulation) model. The SSARR prediction for the 1 March-31 May 1978 time period was within 78% of the spring melt recession period. However, the timing of six observed runoff peaks was off by 2 to 9 days. The magnitude of five of the predicted runoff peaks was within 75% of the recorded streamflow. Additional work on calibrating the basin peak timing and melt rate factors is underway.

The attenuation of electro-optical (BO), infrared (IR), and millimeter wave (MMW) energy through the atmosphere in conditions of low visibility due to the presence of falling or blowing snow can present serious problems for the effective

use of surveillance and target acquisition systems. This paper discusses development of a snow obscuration primer for use by the Smoke and Aerosol Working Group (SAWG) of the Joint Technical Coordinating Group for Munitions Rifectiveness (JTCG/ME). A key part of this primer is incorporation of test results obtained in the SNOW-ONE, ONE-A, and -ONE-B field trials. This includes measurements of falling and blowing snow obscuration effects on BO/IR/MMW systems, both active and passive. An important aspect of this work, reported in this paper, is the evolution of a basis for developing "rules-of-thumb" for operation in air-borne-snow environments.

To test a hypothesis that Landaat reflected radiance values on a regional scale do change, histograms of the Landast MSS band 7 reflected radiance values for a 300 x 300 pixel (420 sq km) area near Allagash, Maine, were evaluated to quantify the change. A statistical description (skewness and kurtosis) of the histogram for each scene was developed and then correlated with ground measurements of anow depth. A snow index based on skewness and modal population was found to correlate well with anow depth. Following these initial results, the Landaat data were reexamined and corrections were made for solar elevation and MSS sensor calibration. The reflected radiance from open arcas showed a consistent increase in intensity with increasing snow depth. The forested land cover classes did not change with snow depth. The ground truth measurements of water equivalent were area-weighted by the May land cover classesfication to derive mean regional water equivalent values for each of the five Landaat winter scenes. The 1 March 1978 estimate of 7.66 inches for mow water equivalent was used as input to the SSARR model for prediction of runoff during the 1 March through 31 May 1978 time period.

COMPUTER APPLICATIONS, MAPPING.
A test site in the Cape Flattery area of northwest Washington state was selected for constructing a simulated data set to evaluate techniques for extracting topography from side-looking satellite systems. A negative transparency orthophotoqued was digitized at a spacing of 85 microa, resulting in an equivalent ground distance of 9.86 m between pixels and a radiometric resolution of 256 levels. A bilinear interpolation was performed on U.S. Geological Survey digital elevation model (DEM) data to generate elevation data a 9.86 m resolution. The nominal orbital characteristics and geometry of the SPOT (Système Probatoire d'Observation de la Terre) satellite were convoluted with the data files to produce simulated panchromatic HRV (Fligh Resolution Visibel) digital stereo imagery for three different orbital paths. Techniques were developed for reconstructing topographic data. Resentially, these techniques coalign a nadir and off-

nadir pass to calculate the stereo displacement for each pixel in the nadir view by correlating a small subares to a corresponding subares in the off-nadir pass. Preliminary analyses with the simulated HRV data and "test pattern" data verify the efficacy

LIME STABILIZATION AND LAND DISPOSAL OF COLD REGION WASTEWATER LAGOON SLUDGE.

38-2506

POROUS MATERIALS, MASS TRANSFER, GROUND WATER, FLUID DYNAMICS, ANAL-YSIS (MATHEMATICS).

YSIS (MATHEMATICS).

A coupled analytical/numerical procedure for prediction of solute transport in heterogeneous media is described. The procedure consists of an analytic solution of the hydraulic equations, followed by a numerical solution for solute transport using the method of characteristics. The characteristics are determined by fourth-order Runge-Kutta and predictor-corrector algorithms. Accuracy of solute transport calculation is enhanced by the fact that fluid velocity can be directly obtained at a priori undetermined points in the flow field. The solute transport process is considered to be entirely advective, neglecting the effects of mechanical dispersion and molecular diffusion. Evidence is presented to demonstrate that purely advective processes in both heterogeneous and homogeneous media can produce large "apparent dispersion." Such dispersion is shown to be easily capable of overwhelming any reasonable estimates of dispersion or diffusion based upon laboratory analyses of homogeneous media. For groundwater contamination problems, it is concluded that precise definition of the spatial variability of hydraulic properties is crucial to the accurate determination of the trajectory of contaminated waters.

PRESSURE RIDGES, ICE FLOES, ICE FORMATION, OFFSHORE STRUCTURES, ICE PRESSURE, ICE STRENGTH, HUMMOCKS, COMPRESSIVE PROPERTIES, SEA ICE.

PRESSIVE PROPERTIES, SEA ICE.

Multi-year pressure ridges and thick hummock floes are the most severe ice formations that offshore structures will probably have to resist in the Beaufort and Chukchi Sosa. Multi-year hummock fields 30 m thick have been measured near Prudhoe Bay, Alaska. This paper presents information on 11 multi-year pressure ridges. The ridges were found to be voidless, and contained ice with a mean brine-free density of about 0.84 mg/cu m.

The apparent unconfined compressive strength was about 7 to 8 MPs at -10 C. The strength increased with depth below sea level, and se expected, varied inversely with ice proresity. The salibeight-to-keel-depth ratios of these ridges are compared with observations made in the Beaufort and Chukchi Seas to show that the multi-year ridges in these areas have a relatively constant sali-height-to-keel-depth ratio of sbout 1 to 3.3.

36-291/ SEA ICE, ICE CORES, ICE COMPOSITION, AL-GAE, CRYOBIOLOGY, FRAZIL ICE, ANTARC-TICA—WEDDELL SEA.

Ite cores obtained during October-November 1981 from Weddell Sea pack ice were analyzed for physical, chemical, and biological parameters. Frazil ice, which is associated with dynamic, turbulent conditions in the water column, predominated (70%). Both floe thickness and salinity indicate ice which is less than 1 year old. Chemical analyses, particularly with regard to the nutrients, revealed a complex picture. Phosphate values are cattered relative to the dilution curve. Nitrate and silicate values are lower than expected from simple scaling with salinity and suggest diatom growth within the ice. Nitrite values are higher in the ice than in adjacent waters. Frazil ice formation which probably concentrates algal cells from the water column into ice floes results in higher initial chlorophyll a by subsequent reproduction within the ice. Ice core chlorophyll ranged from 0.09 to 3.8 mg/cu m, comparable to values previously reported for this area but significantly lower than values for Antarctic coastal fast ice. The dominance of frazil ice in the Weddell is one of the major differences between this are and others. Consequently, we believe that ice structural conditions significantly influence the biological cummunities in the ice. (Auth.) Ice cores obtained during October-November 1981 from Wed-

CIAL ICE.

An experimental study was undertaken to determine the dependence of crushing specific energy of urea ice on the aspect ratio (structure diameter/ice thickness) and the structure velocity. The experiments were conducted by pushing an instrumented, vertical, cylindrical structure into ice sheets at different velocities. Two parameters were varied during the experimental program: diameter (50 to 500 mm) and velocity (10 to 210 mm/s). The urea concentration was changed slightly from 0.84 to 0.93% by weight. The results are presented graphically to show the dependence of the ratio of specific energy to unconfined uniaxial compressive strength on the aspect ratio for different ratios of velocity to ice thickness.

MOISTURE DETECTION, ROOFS, INFRARED PHOTOGRAPHY, TEMPERATURE MEASURE-MENT, INSULATION.

MBNT, INSULATION.

Prior research by the Corps of Engineers has shown aerial thermography to be useful as a reconnaissance tool for finding wet roof insulation. This conclusion was based on findings from thermal line scanners flown at about 1000 feet in military fixed-wing aircraft and from hand-held thermal imagers flown at about 500 feet in military helicopters. During the spring of 1983 a comprehensive serial to on-the-roof infrared comparison study was conducted on several roofs at Fort Devens, Massachusetts. These recent studies confirm our earlier opinion that oblique thermography is generally of reconnaissance value only. However, "straight-down thermography from either fixed-wing aircraft or from helicopt-

ers can be used to produce reasonably accurate maps of wet roof areas. The most accurate maps were produced by thermal imaging systems in a helicopter hovering as close as 200 feet above a roof. This study suggests that some forms of airborne thermography can be of more value than just a reconnaissance tool in finding wet roof insulation. Of course, a visual examination of each roof along with a few core samples are still needed before recommendations

SNOW DEPTH.

Permafrost is generally divided into two zones from north to south: continuous and discontinuous. At its southern limit, permafrost in Alaska exists in isolated masses under peat. In the northern portion of the continuous zone, permafrost occurs everywhere near the surface of the entire landscape with the exception of deep lakes and river channels. The presumed warming of the ground in the discontinuous zone due to CO2-induced climatic change will result in an areal reduction of permafrost. In the colder areas, continuous-zone permafrost temperatures will rise and summer active-layer depths will increase, but the spatial extent of permafrost will only be marginally affected. In both case, where there is ground ice, thermal erosion and thaw consolidation will produce thermolarist terrain.

RIVER FLOW, WAVE PROPAGATION, CHANNELS (WATERWAYS), DAMS, MATHEMATICAL MODELS, ELECTRIC POWER.

CAL MODELS, ELECTRIC POWER.

An understanding of the downstream propagation of sharpfronted, large-amplitude waves of relatively short period is
important for describing rapidly varying flows in tailwaters
of hydroelectric plants and following the breach of a dam.
We developed a numerical model of these waves by first
identifying the primary physical processes and then performing
an analysis of the solution. A linear analysis of the dynamic
open channel flow equations provides relationships describing
flow wave advection, diffusion, and dispersion in rivers. A
one-dimensional diffusion wave model modified for application
to tailwaters simulates the important physical processes and
is straightforward to apply. is straightforward to apply.

ICE-RELATED FLOOD FREQUENCY ANALYSIS: APPLICATION OF ANALYTICAL ESTI-

Gerard, R., et al, International Specialty Conference on Cold Regions Engineering, 3rd, Edmonton, Alber-ta, April 4-6, 1984. Proceedings, Edmonton, Uni-versity of Alberta, 1984₃, p.85-101, 12 refs. Calkins, D.J. 38-347N

FLOOD FORECASTING, RIVER ICE, ICE JAMS, ICE CONDITIONS, ANALYSIS (MATHEMAT-ICS).

ld regions ice-related floods can make a sign and often dominant, contribution to the flood population. They should therefore be considered in a flood frequency analysis. However, in many instances, historical data for this purpose is lacking. Resort must then be made to analytical estimates of ice-related flood stages. This paper describes the determination and application of such estimates for a site on the Missisquoi River near Richford, Vermont.

RIVER ICE, FREEZEUP, ICE FORMATION, ANALYSIS (MATHEMATICS), FORECASTING, AIR TEMPERATURE, WATER TEMPERATURE, CANADA—SAINT LAWRENCE RIVER.

An important element of the ice management in northern rivers is forecasting water temperatures to predict the time

of ice formation. The freeze-up forecast provides needed information for planning flow regulations and scheduling of the close of a navigation season. In this paper, the relationship between variations of sir temperature and water reissionance between variations of air temperature and water temperature is analyzed. An analytical expression for water temperature is obtained through the solution of a simplified convection-diffusion equation. The air temperature is repre-sented as a combination of a harmonic function and short term fluctuations. The short term fluctuations are deter-mined from National Weather Services forecasts.

CRYSTAL STRUCTURE, MODELS, SALINITY. CRYSTAL STRUCTURE, MODELS, SALINITY.

A layer of unfrozen water exists between the soil particle surface and the solid ice phase in a frozen soil at temperatures of practical concern. This layer owes its existence to the effect of field forces associated with the soil particle surfaces. Its thickness depends on factors such as temperature, solute concentration and specific surface area. Additional unfrozen water occurs within the polycrystalline pore ice as well. The thickness of the unfrozen water layer strongly affects the mechanical behavior of the soil-ice interface and, hence, the gross mechanical properties of the frozen soil. The total unfrozen water content is particularly useful since it reflects the contributions from a number of sources to the unfrozen water layer thickness. As a consequence, the unfrozen water content provides an excellent means for temperature, salinity and specific surface area.

In polar regions ice algal communities are not only conspicuous but may also be important production sites and sources of seed populations for pelagic communities. Except for some studies area land-based stations, there are few long-term observations of ice algal populations, and few studies have considered how they form and develop. Duttli now, neither the mechanism for harvesting nor the effects on the composition of the ice community has been clearly demonstrated. In the Weddell Sea, we have sampled young sea ice diacoloured by algae, and we present evidence that the algae were concentrated by a physical mechanism. We explain how such a process may accumulate planktonic forms in ice communities. (Auth. mod.)

(MATHEMATICS).

Le accreted on high-speed rotors operating in supercooled fog can be thrown off by centrifugal force, causing severe unbalance and creating dangerous projectiles. A simple force belance analysis indicates that the strength of accreted ice (and its adhesive strength) can be obtained by measuring the thickness of the accretion, the location of the separation, and the density. Such an analysis was applied to field and laboratory observations of self-shedding events. The results agree reasonably well with other observations.

MP 1720 ASYMPTOTIC BEHAVIOUR OF SOLUTIONS TO THE PROBLEM OF WETTING FRONTS IN ONE-DIMENSIONAL, HORIZONTAL AND INFINITE POROUS MEDIA.

POROUS MATERIALS, SOIL WATER, DIFFU-SION, WETTABILITY, ANALYSIS (MATH-EMATICS), WATER CONTENT, EXPERIMEN-TATION.

TATION.

The saymptotic behavior of solutions to the problem of wetting fronts is studied in one-dimensional, horizontal and infinite porous media with the soil-water diffusivity proportional to some power of the water content. The uniqueness of the similarity solution for the problem is studied and the properties of this solution are presented. It is shown that the similarity solution is an asymptotic solution of a wide class of initial value problems of wetting fronts in the media. The use of the similarity solution is discussed for the experimental determination of the soil-water diffusivity.

SIMILARITY SOLUTIONS TO THE SECOND BOUNDARY VALUE PROBLEM OF UN-SATURATED FLOW THROUGH POROUS

J8-3508 POROUS MATERIALS, WATER FLOW, BOUND-ARY VALUE PROBLEMS, SOIL WATER, DIFFU-SION, WATER CONTENT, ANALYSIS (MATH-EMATICS).

EMATICS).

Similarity solutions to the second boundary value problem of unsaturated flow are studied in one-dimensional, semi-infinite porous media with the soil-water diffusivity proportional to some power of the water content. The existence and uniqueness of two types of similarity solutions to the problem are investigated and the properties of these solutions are presented. It is shown that these two types of similarity solutions exist and that they may not be unique for every parameter range studied. The use of the similarity solutions is discussed for the experimental determination of soil-water diffusivity.

TEMPERATURE STRUCTURE AND INTER-FACE MORPHOLOGY IN A MELTING ICE-WATER SYSTEM.

Yen, Y.-C., Frontiers in hydrology, Littleton, CO, Water Resources Publications, 1984, p.305-325, 22 refs. 38-3800

36-3600 ICE WATER INTERFACE, MELTING POINTS, HEAT TRANSFER, TEMPERATURE DISTRIBUTION, WATER TEMPERATURE, BOUNDARY LAYER, CONVECTION, TURBULENT FLOW.

Nineteen tests were conducted with temperature measurements at various stages of melting experiments. Pourteen sets of photos were taken at various stages of the experiment for melting from above. Formation of concentric ridges was observed only for higher warmer boundary temperatures. However, there were more sharp-edged cavities at lower warm boundary temperatures as compared to those at warmer temperatures. The ice-water interface assemed to be much amoother at the junction of the cells in melting from bove, the convective motions originate near the water-ice interface and therefore, may possess a greater intensity.

EFFECTS OF VOLUME AVERAGING ON SPECTRA MEASURED WITH A LYMAN-ALPHA HY-GROMETER.

Andreas, B.L., Journal of applied meteorology, Apr. 1981, 20(4), p.467-475, 24 refs. 38-3865

HYGROMETERS, HUMIDITY, SPECTROS-COPY, MEASURING INSTRUMENTS, ANAL-YSIS (MATHEMATICS), VOLUME, ACCURACY. YSIS (MATHEMATICS), VOLUME, ACCURACY. Because the Lyman-alpha bygrometer averages turbulent fluctuations in humidity over a right circular cylinder, the spectral response of the instrument degrades at higher wavenumbers. This paper contains a derivation of the three-dimensional spectral averaging function and uses this function, with a new model for the scalar spectrum, to numerically evaluate how this spatial averaging affects measured humidity spectra and humidity variance dissipation rates. In general, hygrometer parameters can be chosen that allow spectral measurements to moderately high werenumbers; but with the size of source and detector tubes currently in use, an accurate measurement of the humidity variance dissipation rate appears impossible. Tobiasson, W. 38-131

CELLULAR PLASTICS, ROOFS, INSULATION, MOISTURE DETECTION, WETTABILITY, TEMPERATURE MEASUREMENT.

MOISTURE DETECTION, WETTABILITY, TEMPERATURE MEASUREMENT.

Infrared scanners are quite successful in finding wet roof
insulation, especially boards of rapidly shoorbing insulations
like perfite, wood fiber and fibrous glass. But wet areas
develop more slowly and nonuniformly in the cellular plastic
insulations, such as wrethane, which are commonly used
in new roofs. These differences can affect the outcome
of an infrared survey of new roofs. To determine the
feasibility of detecting incipient wet insulation, several recently
constructed roofs were examined thermographically. It
was usually more difficult to find moisture in new roofs
containing cellular plastic insulations than in new roofs with
more-absorbent insulations. This increased difficulty is
due to the slower rate of wetting and to the nonuniform
manner of wetting of some of the cellular plastics. Perfite,
wood fiber and fibrous glass insulations tend to become
uniformly wet throughout an entire board, whereas moisture
initially concentrates at the perimeters of boards of some
cellular plastic insulations. However, eight to ten months
after construction, enough moisture can accumulate in most
cellular plastic insulations to be visible to an infrared scanner.
Since this moisture is concentrated in a small portion of
each insulation board, much of it would probably be overlooked
by a nuclear or capacitance grid survey.

TESTS, COMPRESSIVE PROPERTIES.

Creep settlement tests were performed on a strip footing founded on the surface of ice-rich seolian silt permafrost. The tests consisted of applying four step loadings to a 10 in. (25.4 cm) wide concrete footing. The step loads produced constant stresses at the base of the footing of 28, 56, and 111 psi (0.193, 0.385, and 0.770 MPs) for test periods of 12000, 6000 and 3500 hours respectively. The testing was conducted at an ambient temperature of 28.4 F (-2.0 C) in the controlled environment of the USACRREL. Permafrost Tunnel Facility which is located near Pox, Alaska. Settlement and settlement rates of the footing were measured these measured values are compared with those computed by different proposed analytical methods that utilize results from unconfined compression creep tests performed on undis-

turbed soil taken from the testing site. Preliminary results indicate reasonable agreement between computed and measured values.

VERMONT—OTTAUQUECHEE RIVER.

The results of three winters of freeze-up measurements on the Ottauquechee River have shown that the ice production heat transfer coefficient calculated from the ice volume measurements is somewhat related to the severity of the freeze-up meteorological conditions. A very intense cold period of -22 C for two days just as the river water temperature reached 0.0 C produced much higher ice volumes for the same river reach than two other freeze-up periods, which had average air temperatures of -7 C over 10 to 12 days. The intense cold period created higher ice discharges, which forced the leading edge to progress upstream at a faster rate than during other years. The lateral ice closure was found to be linearly related to the number of accumulated freezing degree-days. The data on lateral closure for this

amail river were also related to the freeze-up open channel flow velocity and, when combined with similar data from the Nelson River in Manitoba, produced a reasonable relationship. The sluth ice also established an equilibrium flow area at several measured cross sections throughout the study

FORCE MEASUREMENTS AND ANALYSIS OF RIVER ICE BREAK UP.

ZIL ICE, DESIGN.

Measurements were made near Oil City, Pennsylvania, during February 1981 to evaluate the performance of a floating ice control structure during an ice run on a shallow and steep stream, Oil Creek. The primary objective of the structure was to assist in forming an early, stable ice cover upstream of Oil City that would prevent prolonged frazil ice generation. The control structure was a double timber ice boom. This paper focuses on the forces exerted on the structure during ice breakup. The forces transmitted to the ice control structure prior to breakup and during the ice run were monitored through a strain-gaged tension link, which had been incorporated into the design of the structure, and this ice force was recorded with respect to time.

PREEZING OF A SEMI-INFINITE MEDIUM WITH INITIAL TEMPERATURE GRADIENT.

SOIL FREEZING, STEFAN PROBLEM, HEAT TRANSFER, TEMPERATURE GRADIENTS, GEOTHERMY, HEAT BALANCE, THERMAL CONDUCTIVITY, ANALYSIS (MATHEMATICS). CONDUCTIVITY, ANALYSIS (MATHEMATICS). Exact solutions to problems of conductive heat transfer with solidification are rare due to the nonlinearity of the equations. The heat balance integral technique is used to obtain an approximate solution to the freezing of a semi-infinite region with a linear, initial temperature distribution. The results indicate that the constant temperature Neumann solution is acceptable for soil systems with a goothermal gradient unless extremely long freezing times are considered. The heat balance integral will yield good solutions, with simple numerical work, even for nonconstant initial temperatures.

ICE ACTION ON TWO CYLINDRICAL STRUC-

Kato, K., et al, Journal of energy resources technology, Mar. 1984, 106(1), p.107-112, 17 refs. For another source see 38-641 (MP 1643). Sodhi, D.S.

ICE LOADS, OFFSHORE STRUCTURES, ICE PRESSURE, ICE SOLID INTERFACE, EXPERIMENTATION.

PERIMENTATION.

Ice action on two cytindrical structures, located side by side, has been investigated in a small-scale experimental study to determine the interference effects on the ice forces generated during ice structure interaction. The proximity of the two structures changes the mode of ice failure, the magnitude and direction of ice forces on the individual structure, and the dominant frequency of ice force variations. Interference effects were determined by comparing the experimental results of tests at different structure spacings.

MP 1742 THERMAL PATTERNS IN ICE UNDER DY-NAMIC LOADING.

ICE PHYSICS, DYNAMIC LOADS, HEAT TRANSPER, ICE SPECTROSCOPY, ICE THER-MAL PROPERTIES, PLATES, TESTS.

MAL PROPERTIES, PLATES, TESTS.

Heat emission patterns in the infrared spectrum were discovered in ice subjected to cyclic loading. The ice plates used in the tests had a rectangular shape of 13 x 19 cm and a thickness of 2 cm. The plates were frozen to the platen of the testing apparatus to form a cantilever beam and were vibrated over a frequency range from 0.5 to 5 kHz at an ambient temperature of 4 C. The surface heat patterns were acanned by two thermal imaging systems with spectral band passes of 2.5.6 micron and 3-14 micron, and the heat patterns were recorded on Polaroid film and on videotape. The heat emission patterns first appeared at the fixed end of the ice plate and migrated gradually to the free end. The temperature difference between the ends was found to depend on the duration and frequency of excitation. The results of these tests indicate that vibrothermography can have wide areas of practical application

in the study of the origin and growth of defects, recrystalliza-tion, fatigue, and failure processes in ice.

OFFSHORE OIL IN THE ALASKAN ARCTIC. Weeks, W.F., et al, Science, July 27, 1984, 225(4660), p.371-378, Numerous refs. Weller, G. 38-417

NATURAL RESOURCES, OFFSHORE DRILL-ING, OIL RECOVERY, SEA ICE, ICE LOADS, ICE SCOPING

SCORING.
Oil and gas deposits in the Alaskan Arctic are estimated to contain up to 40 percent of the remaining undiscovered crude oil and oil-equivalent natural gas within U.S. jurisdiction. Most (65 to 70 percent) of these estimated reserves are believed to occur offshore beneath the shallow, ico-covered sees of the Alaskan continents! shelf. Offshore recovery operations for such areas are far from routine, with the primary problems associated with the presence of ice. Some problems that must be resolved if efficient, cost-effective, environmentally safe, year-round offshore production is to be achieved include the accurate estimation of ice forces on offshore structures, the proper placement of pipelines beneath ice-produced gouges in the sea floor, and the cleanup of oil spills in pack ice areas. BOTTOM SEDIMENT, SEDIMENT TRANS-PORT, REMOTE SENSING, WATER POLLU-TION, SPECTROSCOPY, DISTRIBUTION.

TION, SPECTROSCOPY, DISTRIBUTION.
Simulated SPOT (HVR) 20-m multispectral data were obtained on 7 July 1984 over the Hart-Miller Island diked spoil containment facility located in the upper Chesapeake Bay. Sediment plumes were clearly visible and indicated the sediment transport direction at the time the image was taken. The portion of the image along the bay side of the island had strong specular reflection. The image was preprocessed to remove the majority of the specular reflection. The Sobel operator was applied to the enhanced simulated SPOT image. A set of edge segments were generated that follow the boundaries of the major sediment plumes. The strength of the edges was quite variable, reflecting the varying diffusion of the plume border.

The Sobel edge-enhanced image showed two sets of plumes.

The edge intensity was generally stronger neares the source. Profiles of pixel digital number were taken at two distances, normal to the long axes of two sediment source areas.

EFFECTS OF PHASE III CONSTRUCTION OF THE CHENA PLOOD CONTROL PROJECT ON THE TANANA RIVER NEAR FAIRBANES, ALASKA—A PRELIMINARY ANALYSIS. Buska, J.S., et al, Overview of Tanana River monitor-ing and research studies near Fairbanks, Alaska. Pre-

pared by U.S. Army Cold Regions Research and Engipared by U.S. Army Course Regions Research and Engineering Laboratory, U.S. Army Corps of Rugineers, Jan. 1984, 11p. + figs., Appendix A. Barrett, S., Chacho, E.F., Collins, C.M., Young, S.A.

ED STATES—ALASKA—TANANA RIVER.

The Alaska District, Corps of Engineers initiated a program called the Tanana River Monitoring and Research Program to determine if any adverse impacts are occurring or may occur as a result of Phase III construction of the Chena Flood Control Project. The results of the monitoring efforts and a preliminary analysis of the Phase III construction are presented in this report. Aerial photography and river cross-sections were used to document historical changes from 1961 to 1981. Riverbank erosion and channel changes before and after the Phase III construction are evaluated to determine the effects of the construction on the natural river process.

MP 1746 RELATIONSHIPS AMONG BANK RECESSION, VEGETATION, SOILS, SEDIMENTS AND PER-MAPROST ON THE TANANA RIVER NEAR FAIRBANES, ALASKA.

Gatto, L.W., Overview of Tanana River monitoring and research studies near Pairbanks, Alaska. Pre-pared by U.S. Army Cold Regions Research and Engi-neering Laboratory, U.S. Army Corps of Engineers, Jan. 1984, 59p., Appendix B. 30 refs. 38-4208

BANKS (WATERWAYS), SOIL EROSION, FLOOD CONTROL, VEGETATION, PERMA-FROST BENEATH RIVERS, SEDIMENTS, UNIT-ED STATES—ALASKA—TANANA RIVER.

ED STATES—ALASKA—TANANA RIVER.
The objective of this analysis was to determine if available data are useful in identifying the characteristics that contribute to crodibility of the banks along two reaches of the Tanans River. Existing data on bank vegetation, soils, sediments and permafrost were used.

Because these data were general and not collected for the purpose of site-specific analysis, my analytical approach was simple and did not include any statistical tests. The data were visually compared to the locations and estimated amounts of historical recession to evaluate if any relationships were obvious.

ALBEDO, SEA WATER.

Sensitivity simulations of a hierarchy of Antarctic sea ice models to atmospheric warming are carried out and analyzed. The study includes models with only a thermodynamic ice cover, models with in-situ leads but no ice transport, and a fully coupled dynamic thermodynamic model that includes transport, leads and strength-thickness coupling. All models employ a 60-m-thick oceanic mixed layer, together with a spatially and temporally varying heat flux into the mixed layer from the deep ocean. The heat flux was generated layer from the deep ocean. The heat flux was generated interactively by using a fixed fraction of the ice growth and cooling rates from the full dynamic/thermodynamic model. The same spatially and temporally varying heat flux fields were used in all sensitivity simulations. Models including full ice dynamics effects are found to be less sensitive to atmospheric warming than thermodynamics-only models, with a thermodynamics-only models. (Auth. mod.)

PROJECTILE PENETRATION, SNOW COVER EFFECT, MILITARY OPERATION, SNOW DEN-SITY, MILITARY ENGINEERING, PROTEC-TION, PENETRATION TESTS, PHOTOGRAPHY. TION, PENETRATION TESTS, PHOTOGRAPHY.

A soldier on the battlefield is told to "dig in" to protect himsel' against projectiles and fragments. But in cold regions or assaons the ground may be hard, suitable only for deliberate field fortifications built using machines and explosives. However, a winter battlefield scenario often contains an excellent protective material: the snow cover. Often neglected or considered a nuisance, snow can be an obstacle and a disadvantage for the ignorant and a decisive advantage for the properly trained and knowledgesble soldier. Construction of a protective structure made of ordinary snow requires an order of magnitude less effort in time, manpower and energy than is required to obtain the same amount of protection by using sand bags or by "digging in." We have found that small arms projectiles penetrate only 2 m into a snowpile and that protection against recoilless rifte ammunition (HEAT) of the shaped charge type requires the energy to penetration depth relations are complex and that projectile penetrate only described that energy to penetration depth relations are complex and that projectile detonating fuzes may present greater difficulties in snow covered terrain.

MARINE METEOROLOGY, METEOROLOGI-CAL INSTRUMENTS, MEASURING INSTRU-MENTS, BOOMS (EQUIPMENT), SHIPS, AN-TARCTICA

TARCTICA.

We have developed a simple boom for use in measuring meteorological variables from a ship. The main structural member of the boom, a triangular communications tower with rollers attached along its bottom side, is deployed horizontally from a long, flat deck, such as a helicopter deck, and will support a 100-kg payload at its outboard end. The boom is easy to deploy, requires minimal ship modifications, and provides ready access to the instruments mounted on it. And because it is designed for use with the ship crosswind, occanographic work can go on at the same time as the six-sea interaction measurements. We describe our use of the boom on the Mikhall Somov during a cruise into the Antarctic set ice and present some representative measurements made with instruments mounted on it. Theory, experiment, and our data all imply that instruments measurements made with instruments mounted on: I heo-ry, experiment, and our data all imply that instruments deployed windward from a rear helicopter deck can reach air undisturbed by the ship. Such an instrument site has clear advantages over the more customary mast, bow, or buoy locations. (Auth.)

A survey of the synoptic weather patterns and vertical profiles of temperature and humidity over northern Vermont was conducted during periods of snowfall between December 1981 and February 1982. The crystal habit of falling snow, discerned principally from on-site optical microscopy, was also observed during this period. This information was ano observed during this period. This information was used to investigate the association between air mass characteristics and snow crystal types. The ultimate objective of the analysis is to link large-scale weather conditions with the observed physical features of falling frozen particles and with measurements recorded concurrently by electrooptical sensor systems.

This paper contains a detailed description of meteorological conditions (including upper air) of an intense Northeast snowstorm that occurred in mid-December 1981. The paper relates the on-site meteorology to the overall concurrent sysoptic situation. Consideration is given to air mass, hydrometeor intensity, visibility and crystal habit along the SNOW-ONE-A primary line-of-site.

FALLING SNOW CHARACTERISTICS AND EX-TINCTION.

Berger, R.H., U.S. Army Cold Regions Research and Engineering Laboratory. Special report, Mar. 1983, No.83-04, Snow Symposium 2, Vol.1, p.61-69, ADB-073 046, 2 refs. 38-4309

SNOWFALL, LIGHT TRANSMISSION, PARTICLE SIZE DISTRIBUTION, PRECIPITATION GAGES, LIGHT SCATTERING.

OAUSA, LIUTI SCAT IERING.

An examination of the literature shows that a single relationship between the extinction and the precipitation rate does not exist for snow as it does for rain. This is due in part to the wide range of particle sizes and shapes which determine both the optical and mechanical properties of snow. The extinction measurements and extensive move characterization made during the SNOW-ONE and SNOW-ONEA field experiments provide the dats for an examination of the dependence of the estinction on various snow characteristics. The correlations between the extinction and several snow characterization parameters are presented.

VISIBLE PROPAGATION IN FALLING SNOW AS A FUNCTION OF MASS CONCENTRATION AND CRYSTAL TYPE.

Concentrations of orthophosphate, IR1 and IR2 obscurants were measured in surface snow samples after a wintertime test of white phosphorus (WP) smoke and the two infrared exceeders. Sample concentrations of IR1 and IR2 decreased exponentially downwind from the smoke release point. Orthophosphate concentrations were all less than the analytical detection limit of 0.15 mg/L. Quantities of smoke released pose no hazard to the public or environment. Snow was found to provide a clean non-contamination surface means the same of the contamination surface means the contamination surface means. ound to provide a clean non-contaminating surface upon which to collect the deposited aerosol.

ON SMALL-SCALE HORIZONTAL VARIATIONS OF SALINITY IN FIRST-YEAR SEA ICE. Tucker, W.B., et al. Journal of geophysical research, July 20, 1984, 89(C4), p.6505-6514, 20 refs. Gow, A.J., Richter, J.A. 38-4365
SEA ICE VOL.

SEA ICE, ICE SALINITY, BRINES, VARIATIONS. SEA ICE, ICE SALINITY, BRINES, VARIATIONS. Measurements of salinity over horizontal distances of 38 to 76 cm in a thick first-year ice sheet have revealed significant differences. A maximum salinity difference of 2 per mill was observed between ice core segments from the same depth. The mean standard deviation for 10-cm thickness increments through the 2.0-m ice sheet was 0.39 per mill between the five closely spaced cores. The most likely mechanisms for these significant differences in salinity over short distances is differential brine drainage in the ice sheet due to varying locations of brine drainage channels. A simple one-dimensional model which assumes a normally distributed arrangement of brine drainage channels provides results consistent with the horizontal differences observed. (Auth.) ICE COVER MELTING IN A SHALLOW RIVER. Calkina, D.J., Canadian journal of civil engineering, June 1984, 11(2), p.255-265, With French summary. 9 refe

ICE MELTING, RIVER ICE, ICE JAMS, HEAT TRANSFER, FRAZIL ICE, WATER TEMPERA-TURE, RIVER FLOW, FREEZING POINTS, DI-URNAL VARIATIONS, TEMPERATURE DISTRI-BUTTON.

The heat transfer coefficients computed from field data on both ice cover melting and water temperature attenuation are higher than the values one would compute based on extrapolation of previous laboratory flume data. The com-puted heat transfer coefficients were relatively consistent when calculated from the water temperature decay data. Consistent results were also obtained with one set of very detailed ice cover melting data. The disrupt fluctuation when calculated from the water temperature decay data. Consistent results were also obtained with one set of very detailed ice cover melting data. The diurnal fluctuation in water temperature from the freezing point to values of 0.4-0.6 C was associated with the incoming solar radiation and the open water surface area. The measured water temperature distribution beneath the ice cover at a particular cross section varied from 0.2 to 0.6 C due to the influence of frazil ice and flow distribution. In the open water reaches the water temperature was essentially fully mixed vertically but lateral variation across the river ranged from 0.1 to 0.3 C. The average daily melting of the ice cover often exceeded 5.0 cm and at some locations the rate was as high as 8 cm/d. The melt was not uniform across the section but was highly dependent upon the flow conditions, velocity, and depth. The ice cover melting for this year only occurred during the daylight hours as the air temperature likewise decayed to its freezing point.

SURFACE ROUGHNESS OF ROSS SEA PACK

SEA ICE, PACK ICE, ICE SURFACE, MEASURING INSTRUMENTS, ANTARCTICA—ROSS SEA.

SEA.

At the end of the 1980 austral winter, sea-ice surface roughness was assessed along selected tracks in the Ross Sea. The ice surveyed consisted mainly of first-year pack ice. Surface profiles were made using a Spectra-Physica Geodolite 3A laser profilometer which was mounted vertically in the camera bay of a National Science Foundation LC-130 aircraft. The profilometer, recording equipment and measurement technique are described. For the data analyzed to date, the Ross Sea region appears in general to have much less ridging than either the Weddell Sea or the Arctic Basin. The open nature of the boundaries here leads to generally divergent conditions and diminishes the stress transmitted through the pack ice resulting in fewer high ridges. Near coastal boundaries, however, localized high stress may exist and ridging features develop accordingly.

TWO-DIMENSIONAL MODEL OF COUPLED

TWO-DIMENSIONAL MODEL OF COUPLED HEAT AND MOISTURE TRANSPORT IN FROST-HEAVING SOILS.
Guymon, G.L., et al, Journal of energy resources technology, Sep. 1984, 106(3), p.336-343, 30 refs. Hromadka, T.V., II, Berg, R.L. 39.24

HEAT TRANSFER, MOISTURE TRANSFER, FROST HEAVE, SOIL FREEZING, MODELS.

FROST HEAVE, SOIL FREEZING, MODELS.

The model is based unon well known equations of heat and moisture flow in soils. Numerical solution is by the nodal domain integration method which includes the integrated finite difference and the Galerkin finite element methods. Solution of the phase change process is approximated by an isothermal approach and phenomenological equations are assumed for processes occurring in freezing or thawing zones. The model has been verified against experimental one-dimensional soil thawing tank data as well as two-dimensional soil thawing tank data as well as two-dimensional soil seepage data. The model has been applied to several simple but useful field problems such as roadway embankment freezing and frost heaving. (Auth.)

THICKNESS, CLIMATIC FACTORS.

A dynamic-thermodynamic sea-ice model (Hibler 1979) is used to simulate northern hemisphere sea ice for a 20-year period, 1961 to 1980. The model is driven by daily atmospheric grids of sea-level pressure (geostrophic wind) and by temperatures derived from the Russian surface temperature data set. Among the modifications to earlier formulations are the inclusion of snow cover and a multilevel icethickness distribution in the thermodynamic computations. The time series of the simulated anomalies show relatively large amounts of ice during the early 1960s and middle 1970s, and relatively amall amounts during the late 1960s and early 1970s. The fluctuations of ice mass, both in the entire domain and in individual regions, are more persistent than are the fluctuations of ice-covered area. The ice dynamics tend to introduce more high-frequency variability into the regional (and total) amounts of ice mass. The simulated annual ice export from the Arctic basin into the East Greenland Sea varies interannually by factors of 3 to 4.

THERMODYNAMIC MODEL OF CREEP AT CONSTANT STRESS AND CONSTANT STRAIN

Fish, A.M., Cold regions science and technology, July 1984, 9(2), p.143-161, For another source see 38-4470. Refs. p.159-161. 39-339

GROUND MECHANICS, STRESS STRAIN DIA-GRAMS, SOIL CREEP, VISCOUS FLOW, MATH-EMATICAL MODELS, TESTS, LOADS (FORCES).

A thermodynamic model has been developed that describes the entire creep process, including primary, secondary, and tertiary creep, and failure for both constant stress (CS) tests and constant strain rate (CSR) tests, in the form of a unified

constitutive equation and unified failure criteria. Deformation and failure are considered as a single thermoscivated
process in which the dominant role belongs to the change
of entropy. Families of creep curves, obtained from uniaxial
compression CS and CSR tests of frozen soil, respectively
(both presented in dimensionless coordinates), are plotted
as straight lines and are superposed, confirming the unity
of the deformation and failure process and the validity of
the model. A method is developed for determining the
parameters of the model, so that creep deformation and
the stress-strain relationship of ductile materials such as
soils can be predicted based upon information obtained from
either type of test.

TIONS, DENSITY (MASS/VOLUME).
Uniaxial compressive strength tests were conducted on remolded, asturated Fairbanks frozen silt under various constant machine speeds, temperatures and dry densities. Test results abow that the peak strength of frozen illt is not sensitive to dry density (or water content) at 2 C, especially at relatively high strain rates, but is very sensitive to temperature and applied strain rate. However, the failure strain is not sensitive to temperature and strain rate within a wide range of strain, rate, but is very sensitive to dry density. It has been found that the initial yield strength consistently increases with decreasing dry unit weight. The initial yield strain is almost independent of dry density and temperature, but varies with strain rate. The initial tangent modulus of frozen silt is found to be nearly independent of strain rate, but the 50% strength modulus is closely related to strain rate.

The test results indicate that there is a definite relationship between the two moduli.

levestigations of the in situ complex dielectric constant of sea ice were made using time-domain spectroscopy. It was found that (1) for sea ice with a preferred horizontal caxis alignment, the anisotropy or polarizing properties of the ice increased with depth, (2) brine inclusion conductivity increased with decreasing temperature down to about -8

C, at which point the conductivity decreased with decreasing temperature, (3) the DC conductivity of sea ice increased with increasing brine volume, (4) the real part of the complex delectric constant is strongly dependent upon brine volume but less dependent upon the brine inclusion orientation, (5) the imaginary part of the complex delectric constant was strongly dependent upon brine inclusion orientation but much less dependent upon brine inclusion orientation but much less dependent upon brine volume.

—WEDDELL SEA.

This paper presents the results of an investigation of microspherules found in snow and pack ice from the Weddell Sea, Antarctica, collected during the U.S.-U.S.S.R. Weddell Polynya Expedition, 1981.

Bemental composition, size, and concentration of microspherules were determined using a scanning electron microscope (SEM) and energy dispersive X-ray analysis (BDXA). Typical textures of microspherules are shown in this report and compared with those found in anow and ice-fog crystals sampled from the Northern Hemisphere. In this study, 23 microspherules were found in the snow sample from the Weddell Sea and 6 from the snow-ice sample. The concentration of microspherules in the snow samples is calculated to be approx 0.001 percent, three orders of magnitude smaller than that of the Northern Hemisphere. This indicates that the concentration of microspherules in the Antarctic may be three orders of magnitude smaller than that Silicon—and titanium-rich microspherules from the Weddell Sea were found in thy and of terrestrial origin.

The iron rich microspherules were tentatively identified to be of extraterestrial origin.

DELL SEA.

In Oct. 1981 the U.S.-USSR Weddell Polynya Expedition crossed the Antarctic marginal ice zone (MIZ) near the Greenwich Meridian on the Michail Somov. Five radiosondes, Isunched along a 150-km track starting at the ice edge, showed profound modification of the atmospheric boundary layer (ABL) as increasing surface roughness decelerated the flow. An equation is presented for the dependence of the drag coefficient on ice concentration that should be useful for modeling the surface stress in marginal ice zones. The sounding profiles and meteorological data provided a comprehensive look at how surface roughness and temperature changes in the MIZ can affect the ABL.

GY, ANTARCTICA—WEDDELL SEA.

Diatoms were found throughout the length of sea ice cores (average length, 75 cm) taken from the Weddell Sea during the Oct.-Nov. 1981 joint U.S.-U.S.S.R. study. As in previous studies it was found that the pennate forms were dominant. Chaetoceros dichaeta Ehrenberg was the only centric species which was "abundant" in the samples, and it has not previously been reported as abundant. Of the pennate species found in abundance, three have been found in abundance by other authors. These are Nitzachis colsterium (Bhrenberg) W. Smith, Nitzachis cylindrus (Grunow) Hasle, and Nitzachis subcurvats Hasle. Also found to be numerically significant in the samples were Nitzachis prolongatoides Hasle, Nitzachis unidentified Navicula species. The table lists the dominant species in each sample and their relative abundances. Five of these species have not previously been found in abundance retices have not previously been found in abundance retic sea ice. Possible reasons for the variable compositions in samples are discussed.

MP 1787 RESERVOIR BANK EROSION CAUSED BY ICE

ICE EROSION, BANKS (WATERWAYS), RESER-VOIRS, ICE CONDITIONS, WATER LEVEL, BOTTOM SEDIMENT, SHORE EROSION.

BOTTOM SEDIMENT, SHORE EROSION.

The purpose of this study was to evaluate the documented and potential importance of ice erosion along reservoir banks. The evaluation is based on a literature review and on inferences drawn from field observations and experience. Very little is known about the amount of reservoir bank erosion caused by ice action, although considerable information exists on occ erosion processes along the shorelines and beaches of oceans, rivers and lakes. The importance of ice-related erosion along a reservoir bank would depend primarily on water level, but ice conditions and bank sediment characteristics would also be important. If the reservoir water level is at bank level, ice could directly erode a bank face. If the water is below the bank, ice would have no direct effect on it. However, ice could indirectly increase bank instability by disrupting and eroding nearshore and beach zones, which could lead to bank erosion.

DRAULIC STRUCTURES.

Measured ice stress data are needed to verify and improve thermal ice thrust prediction models used in estimating ice forces on dams, bridge piers, locks and other hydraulic structures. During February and March, 1983, thermal ice pressures were measured in the ice on a small lake in central New Hampahire. Byen though the ice sheet was relatively warm and only exhibited small changes in temperature, stresses up to 200 to 300 kPa were recorded with a newly designed biaxial ice-stress sensor. Ice stresses normal and parallel to the shore of the lake were similar. Given the rate of change of temperature of the ice, ice pressures were calculated for the measurement period using a uniaxial rheological model consisting of a spring and nonlinear dashpot connected in series. Calculated and measured stresses were in good agreement.

ERTIES, GROUND THAWING.

Small ferromagnetic particles in soils locally change the magnetic field of a nuclear magnetic resonance (NMR) snalyzer. This causes a decrease in the NMR signal intensity when NMR is being used to measure unfrozen water contents in partially frozen soils or total water contents in hawed soils. We mixed Tuto clay, a soil containing no magnetic particles, with various small amounts of pure powdered magnetite, and determined the NMR signal intensity while the samples were both thawed and partially frozen. Then we derived an equation that correlates the thawed sample signal intensity with the weight percent of powdered magnetite added. The unfrozen water content of the partially frozen samples could be determined accurately for samples containing up to 0.2 to 0.3% magnetize. Several methods for demagnetizing soils containing large amounts of magnetic particles were tried, with the most effective found to be stirring a slurry of the soil over a powerful permanent magnet. Accurate unfrozen water contents could be determined for all the partially frozen samples is ome form of demagnetizing procedure was used on those samples containing the most magnetic particles.

ING.

The snow and glacial ice on permanent snowfields must serve as both the water source and the receptacle for wastes for any human habitation. In addition, the snow also serves as the support media for any structural foundations and hence the thermal aspects of water supply and waste disposal can be critical. Most activity has occurred on the ice caps of Greenland and Antarctics and has ranged from small transient field parties to large permanent facilities in continuous use for over 25 years. Novel procedures to insure the reliable production of good quality water are described as well as the recommended criteria for water quantity depending on the size and duration of the activity. The various methods of wastewater disposal that have been used at temporary camps and permanent stations are described along with the results from studies that defined the faste of the wastewater following its discharge to the snow. Such definition is important to insure protection of the water supply as well as the thermal integrity of any structural foundation.

ICE JAMS, RIVER ICE, FLOODING, ICE CONDITIONS, FREEZEUP, ICE COVER THICKNESS, ICE CONTROL, MODELS, UNITED STATES—IDAHO—SALMON RIVER.

A study was undertaken to document the ice conditions leading to the ice jam flooding along the Salmon River in the vicinity of Salmon, Idaho. This short paper documents the ice conditions on the river during the freeze-up period and the simple analytical model used to predict the advance of the ice cover leading edge. Ice cover thickness in excess of 9 ft. 3 m) were measured at cross sections where shoving had occurred. The initiation of the ice cover for this resch of the river begins in a long, deep poof formed by an alluvisi fan from Dump Creek that developed in the late 1800's. By improving the flow conveyance through the alluvial fan and increasing the flow velocity in the backwater behind it, the initiation of the freeze-up ice cover could be delayed, thereby delaying the arrived the leading edge at Salmon, Idaho, and reducing the potential for ice jam flooding.

MP 1797 MODELING INTAKE PEFORMANCE UNDER FRAZIL ICE CONDITIONS.

Dean, A.M., Jr., Conference con; Water for Resource Development, Coeur d'Alene, Idaho, Aug. 14-17, 1984. Proceedings, 1984, p.559-563, 5 refs. 39-616

WATER INTAKES, FRAZIL ICE, ICE CONDI-TIONS, WATER PIPES, ICING, MODELS, COUN-TERMEASURES.

TERMRASURES.

A water intake was modeled in a refrigerated flume in an active frazil icing environment in order to evaluate alternative modifications to the prototype structure. Conduit dimensions tested were 2.7-in. round, 4.6-in. round, 6-in. aquare, nan 12-in. square. Entrance shapes tested were square, quarter-rounded, and elliptical. Model flows varied from 50 gpm to 360 gpm, resulting in average model intake velocities of 0.8 fps to 2.8 fps. Corresponding Proude prototype velocities varied from 0.3 fps to 2.0 fps. The length scale varied from 1.6.5 to 1:16. Tests were run until a head was developed across the model intake which was equivalent to a 12-foot head on the prototype, or until the icing tendency of the structure was determined. The icing mechanism observed in the model included stoppering of the intake with ce masses, restriction of the intake with multiparticle masses, and gradual accumulation of frazil ice particles on the intake.

39-801 SNOW COVER DISTRIBUTION, SNOW WATER EQUIVALENT, RIVER BASINS, REMOTE SENS-ING, SNOWMELT, VEGETATION FACTORS, LANDSAT, ACCURACY, COMPUTER APPLICA-TIONS, MODELS, MAPPING.

TIONS, MODELS, MAPPING.

Two methods for computing basin areal average water equivalent of the enowpack based on point snow course measurements are discussed. One involves the use of a square grid databank of elevations and vegetation types which are regressed against snow water equivalent. The other method utilizes digital tapes of LANDSAT satellite imagery to delineate various vegetation categories throughout a basin. Snow-course values obtained within a given vegetation category are then distributed over the area within each basin which contains that category of vegetation. Where possible, the methods were checked by deriving snowpack values for six basins in the Upper Saint John River basin for the spring of 1978. These values were then used as input to the SSARR model, and the resulting runoff hydrographs were compared to those obtained using the conventional "isoline mapping" method of distributing the snowcourse values. Lastly, a range of errors were introduced into the conventionally derived snowpack values, and the resulting range in errors of the runoff hydrographs were computed to determine the sensitivity of the SSARR model to errors in snowpack input. MELTWATER, UNITED STATES—ALASKA—MATANUSKA GLACIER.

Subaerial sediment flow is the predominant process depositing diamictons at the terminus of Matanuaka Glacier. Flows originate where sediments overlie glacier ice. Ablation of ice exposed in slopes disaggregates the overlying sediment and mixes it with meltwater and debris released simultaneously. This material generally flows only after its strength is further reduced by excess pore pressures and seepage pressures generated by meltwater from thawing ice. Moving sediment flows show reasonably systematic changes in physical attributes such as dimensions, texture, flow rates, density and erosional action, and in grain support and transport mechanisms that can be related to changes in the water contents of their matrix material. At lowest water contents, flows support grains by their strength and move through shear in a thin zone at their base. Increased thicknesses of the zone in shear and deformation of other types accompany increased water contents, with grain interference and collisions, localized liquefaction and fluidization, transient turbulence, and bediend traction and saltation operating simultaneously in such moving flows. At highest water contents, flows appear fully liquefied. The fluidity of the sediment flow and the amount of water in the sediment flow channel determine the degree of preservation of the source flow's properties and the depositional morphology. Because mobilization of a sediment flow destroys the glacial sedimentary properties of its sediment flow destroys the dismitute of the mechanics of transport and deposition develop new "non-glacial" properties in this sediment, the dismitute of the desiment flow should not be called till.

SILE, IESIS, IBMPERATURE EPPECIS.

A series of unconfined compression crept tests was conducted on anturated frozen Fairbanks silt at constant-atress and constant-temperature conditions. The authors suggest that the creep of frozen soil be classified into two types: short-term and long-term creep. Different constitutive and strength-lose equations are presented for each type of creep. On the basis of Assur's creep model (1980) and this criterion, a creep equation was derived that can describe the entire process of creep of frozen soil.

39-1400 ICE FORMATION, ICE COVER THICKNESS, RIVER ICE, RIVER FLOW, HEAT TRANSFER, ICE JAMS, HYDRAULICS, COMPUTERIZED SIMULATION, ANALYSIS (MATHEMATICS), CANADA—SAINT LAWRENCE RIVER.

A computer model was developed for simulating the formation of ice cover in the Upper St. Lawrence River. The model included submodels for the river flow condition, the distribution included submodels for the river flow condition, the distribution of water temperature or frazil ice production, and the formation of an ice cover. Distributions of water temperature or ice production are determined by a Lagrangian solution of the equation for the transport of thermal energy subject to surface heat exchange. The formation of an ice cover and ice accumulations is formulated according to existing equilibrium ice jam theories. The hydraulic condition in the river system is determined by an implicit numerical solution of unsteady continuity and momentum equations.

A numerical model of the flow and ice conditions during freeze-up for the Ottauquechee River has been developed and calibrated with reasonable success. A limited sensitivity analysis of the key ice hydraulic modeling coefficients and independent variables was undertaken to examine their effect on the rate of leading edge progression, ice thicknesses and water levels. The criteris for advancement of the leading edge were based on both the entrainment velocity of incoming frazil slush at the leading edge and whether or not the flow condition was sub-critical just upstream of the leading edge. The depositional mode of ice thickness in the steep reaches and over 80% in 1 km of the pool. The simulation suggests that the initial ice cover thickness during progression can be predicted using the equilibrium ice jam theory with a suitable cohesion coefficient. The inflow ice discharge and ice generated within the reach modeled were important and have to be known with reasonable accuracy to get good simulations of the ice thicknesses, water levels and ice cover progression.

FRAZIL ICE, RIVER ICE, ICE MECHANICS, VELOCITY, TESTS, ARTIFICIAL ICE.

VELOCITY, TESTS, ARTIFICIAL ICE.

The objective of this study was to examine the rise pattern and velocity of frazii ice. In addition, discs made of other materials were employed both to facilitate this study and to aid in the development of artificial frazii for future transport studies. The rise velocity is a parameter important to the understanding of frazii entrainment, transport and deposition. Laboratory tests were conducted in a large clear plastic cylinder at controlled temperatures. The rise velocity of real frazii is compared with theory and given an indirect verification that the preferential crystal growth direction increases disc diameter while the thickness remains essentially constant. The effective drag coefficients and rise pattern stability are discussed in terms of a Reynolds-Strouhal number relationship. The results from real and artificial frazii experiments are compared, and criteria for frazii simulation are suggested.

RADAR MEASUREMENTS OF BOREHOLE GEOMETRY ON THE GREENLAND AND AN-TARCTIC ICE SHEETS.

Jezek, K.C., Geophysics, Feb. 1985, 50(2), p.24 251,

GLACIER FLOW, RADAR ECHOES, BORE-HOLES, ICE SHEETS, ICE MECHANICS, GLACIER OSCILLATION, GREENLAND, ANTARC-TICA—DOME C.

A method for measuring the geometry of boreholes in glaciers has been developed and tested in Greenland and Antarctica. Coordinates of points along the borehole are determined by lowering a passive radar target into the borehole and then tracking the target from three surface stations. Comparison of geometry interpreted from radar data and from a conventional inclinometry experiment indicates that radar data can be used to estimate average borehole inclination and azimuth but cannot be used to measure details of the and azimuth but cannot be used to measure details of the borehole geometry that are revealed by conventional inclinometry surveys. Random error introduced by variations in the physical properties of the glacier and electrical noise in the radar unit limit measurement accuracy, but the accuracy can be improved by establishing additional surface radar stations around the borehole. These experiments demonstrate the utility of the radar method and suggest the possibility of deploying permanently installed radar targets in ice sheets to measure intraglacial movements. (Auth.)

TAL IMPACT, THAW DEPTH, TESTS.

Traffic tests were conducted at two sites in northern Alaska with an air cushion vehicle, two light tracked vehicles, and three types of wheeled Rolligon vehicles. The traffic impact (surface depression, effect on thaw depth, damage to vegetation, traffic signature visibility) was monitored for periods of up to 10 years. Data show the immediate and long-term effects from the various types of vehicles for up to 50 traffic passes and the rates of recovery of the active layer. The air cushion vehicle produced the least impact. Multiple passes with the Rolligons caused longer-lasting damage than the light tracked vehicles because of their higher ground contact pressure and wider area of disturbance. Recovery occurs even if the initial depression of the tundra surface by a track or a wheel is quite deep (15 cm), as long as the organic mat is not sheared or destroyed.

TEMPERATURE EFFECTS, SHEAR STRESS.

In the growing field of ice engineering there is a need o establish standardized model tests of structures for use in environments. This study was designed to investigate the relative influence of various parameters on the kinetic friction coefficient between ice and different surfaces and determine which of those variables would need future, incepth investigation. Friction tests were performed with urea-doped, columnar ice, and the parameters of normal pressure, velocity, type of material, material roughness, ice hardness and test configuration were studied. Tests were conducted by pulling a loaded sample of ice over a sheet of material and by pulling a loaded sample of material over an ice sheet. An ambient temperature of -1.5C was maintained throughout the testing process, and the ice surface hardness was measured using a specially designed apparatus. The experimental results of the friction tests revealed that the behavior of the friction coefficient with varying velocity was significantly influenced by the test configuration and material roughness. Its magnitude was also affected by varying normal pressure, ice hardness, surface roughness and type of material.

FLEXURAL STRENGTHS OF FRESHWATER

Gow, A.J., IAHR International Symposium on Ice, 7th, Hamburg, F.R.G., Aug. 27-31, 1984. Proceedings, Vol.1, [1984], p.73-82, 4 refs. 39-1757

ICE STRENGTH, FLEXURAL STRENGTH, LAKE ICE, ICE CRYSTAL STRUCTURE, ICE TEMPERATURE, GRAIN SIZE, TESTS.

In this paper we present results of small beam tests performed on simulated lake ice corresponding in structure to the two major ice types, S1 and S2, encountered in lake ice covers. In these tests a combination of cantilever and simply supported beams was used to ascertain the dependence of flexural strength of the ice on its structure and temperature. It was found that macrocrystalline (S1) ice and columnar (S2) ice exhibit significant differences in bending strength and that substantial stress concentrations exist at the fixed corners of cantilever beams. Differences in response of S1 and S2 ice to bending forces clearly reflect variations in grain size, crystal orientation, temperature, and temperature gradient in the simulated ice, and these factors must be carefully considered when interpreting results of tests of the flexural strength of natural ice covers.

MP 1827 ICEBREAKING BY GAS BLASTING.

Mellor, M., IAHR International Symposium on Ice, 7th, Hamburg, F.R.G., Aug. 27-31, 1984. Proceedings, Vol. 1, [1984], p. 93-102, 6 refs. 39-1759

TURES, EQUIPMENT.

Icobreaking tests utilizing high pressure air and CO(2), low pressure air, and fuel/oxidant combustion are reviewed and the results are interpreted. Applying cube root energy scaling to test discharges of approximately 1 MJ, it appears that fracture craters up to about 5.8 m/MIJ(1/3) in diameter can be formed by optimum underwater blasts. Practical systems for clearing or displacing ice could be based on air guns developed for offshore sciamic work, with gun pressure in the range 17-20 MPs and single-gun energy up to about 11 MJ. A procedure for making preliminary design calculations and safety appraisals is outlined, and it is concluded that a working "Super-Bubbler" need not be very complex or expensive.

QUIET FREEZING OF LAKES AND THE CON-CEPT OF ORIENTATION TEXTURES IN LAKE

Gow, A.J., IAHR International Symposium on Ice, 7th, Hamburg, F.R.G., Aug. 27-31, 1984. Proceedings, Vol. 1, 1984, p.137-149, 6 refs. 39-1763

39-1763

LAKE ICE, ICE CRYSTAL STRUCTURE, ICE NUCLEI, FREEZING, TURBULENCE, TESTS.
Several years' observations of the crystaline structure of
ice sheets forming on a number of New England lakes
indicate that just two major types of congelation ice are
formed during quiet (non-turbulent) freezing of lake water.
These are: (1) ice sheets characterized by the growth of
massive prismatic crystals exhibiting vertical or near-vertical
c-axes probably equivalent to so-called SI ice and (2) ice
sheets composed predominantly of vertically elongated crystals
exhibiting horizontally oriented c-axes, so-called columnar
ice or S2 ice. In this context of quiet freezing of lakes
it was also determined that columnar textures are always
associated with horizontal c-axis orientations of the crystals,
whereas the development of c-axis vertical orientation is
invariably linked with the growth of massive crystals. These
observations have fostered the concept of orientation textures.

DYNAMICS OF FRAZIL ICE FORMATION.

Daly, S.P., et al, IAHR International Symposium on Ice, 7th, Hamburg, F.R.G., Aug. 27-31, 1984. Proceedings, Vol.1, [1984], p.161-172, 10 refs. Stolzenbach, K.D.

FRAZIL ICE, ICE CRYSTAL GROWTH, HEAT TRANSFER, MATHEMATICAL MODELS, MASS TRANSFER, SURFACE PROPERTIES, ICE CRYS-

TAL NUCLEI.

This paper applies quantitative approaches of large-scale industrial crystallization to the study of frazii ice. The development of a crystal number continuity equation and a heat conservation equation can serve as a basis for predicting size distribution and concentration of frazii crystals. The key parameters in these equations are the crystal growth rate and the rate of secondary nucleation. The crystal growth rate is determined by the heat transfer rate from the crystals to the fluid, the intrinsic kinetics of the crystals surface tension and the mass transfer rate of secondary nucleation. the crystals to the fluid, the intrinsic kinetics of the crystals, surface tension, and the mass transfer rates. Available data indicate that the growth of the major axis of frazil crystals is controlled largely by heat transfer. The heat transfer supersection of disks suspended in turbulent flow is presented. The rate of secondary nucleation can be expressed as the product of three functions, which relate the energy transferred to crystals by collision. The secondary nucleation rate is found to be a function of the turbulent energy dissipation and a strongly nonlinear function of the form and magnitude of the crystal size distribution. The number continuity and heat conservation equations are troublesome to solve simultaneously because they are nonlinear and dimensionally incompatible. However, the equations can be used in the development of models of frazil ice formation.

ICE CONTROL, STRUCTURES, ICE SHEETS, ICE BOOMS, ICE FORMATION, ICE COVER, COUNTERMEASURES, WATER FLOW.

TERMEASURES, WATER FLOW.

Ice sheets are formed and retained in several ways in nature, and an understanding of these factors is needed before most ice sheet retention structures (not and are somewhat flexible; others are fixed and rigid or semingid. An example of the former is the Lake Erie boom and of the latter, the Montreal ice control structure. Ice sheet retention technology is changing. The use of timber cribe is gradually but not totally giving way to sheet steel pillings and concrete cells. New structures and applications are being tried, but with caution. Ice-hydraulic analyses are helpful in predicting the effects of structures and channel modifications no ice cover formation and retention. Often, varying on ice cover formation and retention. Often, varying the flow rate in a particular system at the proper time will make the difference between whether a structure will or will not retain ice. The structure, however, invariably adds reliability to the sheet ice retention process.

MAY 1833 ANALYSIS OF RAPIDLY VARYING FLOW IN ICE-COVERED RIVERS. Perrick, M.G., IAHR International Symposium on Ice, 7th, Hamburg, F.R.G., Aug. 27-31, 1984. Pro-ceedings, Vol.1, [1984], p.359-368, 6 refs. 39,1783 39-1783

ERS.
Rapidly varying flow waves are a primary cause of ice cover breakup on rivers.

and the difficulties involved in determining conditions in the field, analyses of river waves during breakup are subject to much uncertainty. We conducted laboratory experiments to determine the effects of the ice cover upon these waves, and to identify the physical processes that produce these effects. The dimensionless friction scaling parameter of the St. Venant equations provides a quantitative estimate of the friction/inertia balance that dictates river wave behavior. Knowledge of this balance is essential to interpretation and analysis of flow wave data. In this paper we apply the friction parameter in our interpretation of the laboratory data and address discrepancies between data and previous analyses of an ice jam release on the Athabasca River.

CRYSTALLINE STRUCTURE OF UREA ICE SHEETS USED IN MODELING IN THE CRREL TEST BASIN.

Gow, A.J., IAHR International Symposium on Ice, 7h, Hamburg, F.R.G., Aug. 27-31, 1984. Proceedings, Vol.2, [1984], p.241-253, 13 refs. 39-1807

ICE CRYSTAL STRUCTURE, UREA, CIAL ICE, MICROSTRUCTURE, ICE MODELS, SEA ICE, ICE STRENGTH, ICE SHEETS, TESTS. Standard petrographic techniques were used for studying microstructure in thin sections of urea ice sheets now being used extensively in the CRREL Test Basin for modeling sea ice. Depending mainly on the seeding techniques employed and partly on the thermal condition in the column of urea-doped water two kinds of ice with radically different structural and mechanical properties have been identified. In the one exhibiting vertical c-axis structure minimal urea is incorporated into the ice crystals, and ice sheets with this kind of structure tend to remain "strong" even after the temperature of the ice is raised close to its melting point. Ice of the second type is characterized by a preponderance of crystals exhibiting horizontal c-axes. This kind of ice, which is only produced when the test basin is seeded prior to freezing, also contains abundant inclusions of urea systematically incorporated into the crystals; the overall columns retructure of this ice closely resembles that of ordinary sea ice and optimum test conditions for modeling purposes are usually obtained with warm isothermal ice sheets of the latter type. SEA ICE, ICE STRENGTH, ICE SHEETS, TESTS. are usually

SIZE, FINES.

An equation accurately describing the rate of frost heave is derived by using the mixture theory of continuum mechanics. It is shown that the rate of frost heave is determined mainly by the rate of heat removal and the rate of water intake. When the phase equilibrium holds in the system, the relation between the rate of heat removal and the rate of water intake is shown to depend mainly on the phase composition data of a given medium. By studying reported experimental data, it is found that the phase equilibrium may hold until the rate of heat removal reaches a certain critical value. When the rate of heat removal exceeds this critical value, the phase equilibrium may possibly be disrupted for some media.

WATER TRANSPORT, FROZEN GROUND, GROUND ICE, SOIL WATER MIGRATION, DIFFUSION, ANALYSIS (MATHEMATICS).

Effects of ice content on the transport of water in frozen soil are studied experimentally and theoretically under isothermal conditions. A physical law, that the flux of water in unsaturated frozen soil is proportional to the gradient

of total water content is proposed. Theoretical justification is made by the use of the two-phase flow theory. The experimental results are shown to support the proposed physical law. The results of this study are presented in two parts and this is the second paper describing the theoretical aspects of the study

GLACIER ICE, RHEOLOGY, ICE SHELVES, STRAINS, ICE MECHANICS, ANTARCTICA--ROSS ICE SHELF.

ROSS ICE STIELT.

A new method for calculating the stress field in bounded ice shelves is used to compute strain rate and deviatoric stress on the Ross Ice Shelf, Antarctica. The analysis shows that strain rate (per second) increases as the third power of deviatoric stress (in newtons per square meter), with a constant of proportionality equal to 2.3 x 10 to the -25th power. PRESSURE RIDGES, ICE CRYSTAL STRUC-TURE, ICE STRENGTH, COMPRESSIVE PROP-ERTIES, STRAINS, SEA ICE, TEMPERATURE EFFECTS, POROSITY, TESTS.

A series of 222 uniaxial constant-strain-rate compression tests was performed on vertical multi-year pressure ridge sea ice samples. A preliminary analysis of the effect of structure on the compressive atrength of the ice was performed on 78 of these tests. Test parameters included a temperature of -5C (23F) and strain rates of 1/100,000 and 1/1,000/s. Columnar ice loaded parallel to the elongated crystal axes and perpendicular to the crystal c-axis was consistently the strongest type of ice. The strength of the elongated crystals approached the plane of maximum shear. Samples containing granular ice or a mixture of granular and columnar ice resulted in intermediate and low strength values. No clear relationship could be established between structure and strength for these ice types. However, in general, their strength decreased with an increase in porosity.

CONSTRUCTION.

To date, the water-retaining structures constructed and maintained on permatrost in North America have been designed and built using a combination of soil mechanics principles for unfrozen soils and unproven permafrost theory. In the USSR, at least five sizeable hydroelectric and water supply embankment dams as well as several small water supply embankment dams have been constructed and maintained on permafrost. The larger dams are understood to have performed well, but the smaller dams have been a mix of successes and failures. Specific criteria are still lacking for design, operation, and post-construction monitoring of water-retaining embankments founded on permafrost. The purpose of this presentation is to review the current practice, point out how it is deficient, and note what major problems need attention.

ANALYSIS (MATHEMATICS).

Subgrade cooling methods in cold regions include the use of thermosyphons with inclined evaporator sections. This laboratory study was conducted to determine the thermal performance characteristics of a thermosyphon. Evaporator inclination angles ranged from 0 to 12 deg from the horizontal. A standard full size thermosyphon, charged with carbon

dioxide, was tested in CRREL's atmospheric wind tunnel. Empirical expressions are presented for heat removal rates as a function of wind speed and ambient air temperature for each of the inclined evaporator angles. An approximate analytical method is also presented for foundation thermal design using thermosphons under buildings with a slab-on-grade foundation. Heat gains from the alab to the thermosphon as well as the evaporator temperature are presented as functions of time.

While many materials undergo phase change at a fixed temperature, soil systems exhibit a definite zone of phase change. The variation of unfrozen water with temperature causes the soil to freeze or thaw over a finite temperature range. Exact and approximate solutions are given for conduction phase change of plane layers of soil with water contents that vary linearly, quadratically, and exponentially with temperature. The temperature and phase change depths are found to vary significantly from those of the constant temperature or Neumann problem.

THICKNESS, DYNAMIC LOADS, ICE DEFORMATION, VELOCITY, TESTS.

MATION, VELOCITY, TESTS.

To determine the characteristic length of a floating ice sheet, the deflection of the ice sheet must be measured in response to a known load. Deflection measurements with a deflectioneter require reference to a fixed datum. A simple deflection measuring technique is described here that is based on integration of the response of a sensitive slope transducer to a moving load at constant speed. This procedure does not require reference to a fixed datum; instead the gravitational field acts as the datum. The characteristic lengths obtained from the slope-integration method compare very favorably with those obtained from direct measurement of deflections.

GRAIN SIZE AND THE COMPRESSIVE STRENGTH OF ICE.

Cole, D.M., International Offshore Mechanics and Arctic Engineering Symposium, 4th, Dallas, Texas, Feb. 17-21, 1985. Proceedings, Vol.2, New York, American Society of Mechanical Engineers, 1985, p.220-226, 15 refs.

ICE STRENGTH, COMPRESSIVE PROPERTIES, GRAIN SIZE, STRESS STRAIN DIAGRAMS,

This work presents the results of uniaxial compression tests on freshwater polycrystalline ice. Grain size of the test material ranged from 1.5 to 5 mm, strain rate ranged from 1/1,000,000 to 1/100/s and the temperature was -5 C. The grain size effect emerged clearly as the strain rate increased to 1/100,000/s and persisted to the highest applied strain rates. On average, the stated increase in grain size brought about a decrease in peak stress of approximately 31%. The occurrence of the grain size effect coincided with the onset of visible cracking. The strength of the material increased to a maximum at a strain rate of 1/1,000/s, and then dropped somewhat as the strain rate increased further to 1/100/s. Strain at peak stress generally tended to decrease with both increasing seven decrease. 1/100/s. Strain at peak stress generally tended to decrease with both increasing grain size and increasing strain rate. The results are discussed in terms of the deformational mechanisms which lead to the observed behavior.

ICE LOADS, STRESS' S, MEASURING INSTRUMENTS, LOADS (FON-CES), DESIGN, TESTS.
An elongated, uniaxial brass ice stress sensor has been developed by the University of Alaska and used in several field
experiments. Laboratory calibration tests have been conducted, in a 60 x 29.5 x 8.5 in, 1524 x 750 x 216 mm)
ice block into which the sensor was frozen, to determine
the sensor's response characteristics. Test results indicate
that the sensor acts as a stress concentration with a stress
concentration factor of 2.4 and transverse sensitivity of 1.3 at stresses below 30 lbf/sq in (207 kPs). At stresses
greater than 30 lbf/sq in the stress concentration factor
increased and the sensor exhibited a time delay response
to load. Differences of 22% were measured between the
measured sensor stress immediately after a constant ice load
was applied and the symptotic stress limit. Interpretation
of measured sensor stresses can be considered reliable at
ambient ice stress levels below 30 lbf/sq in.

MP 1860 CALIBRATING CYLINDRICAL HOT-FILM ANEMOMETER SENSORS.

Andreas, E.L., et al. Journal of atmospheric and oceanic technology, June 1986, 3(2), p.283-298, Refs. p.298. Murphy, B. 40-4484

ANEMOMETERS.

ANEMOMETERS.

We report the results of 82 separate calibrations of cylindrical, platinum hot-film anemometer sensors in air. The calibrations for each sensor involved a determination of its temperature-resistance characteristics, a study of its heat transfer in forced convection, and an investigation of its yaw response. The convective heat transfer relation that we derive predicts the Nusselt number of the sensor as a linear function of e.g. 0.40, where R is the Reynolds number based on sensor diameter (1<R<43). For the 53 micrometer diameter ere sensors that we used, this heat transfer relation applies to wind speeds typical of the atmospheric surface layer, 1 to 20 m/s. From the heat transfer relation we also devise a usehod for determining hor-film operating characteristics at temperatures other than the calibration temperature. Hinze's relation is the best model for the yaw response of these sensors, being valid over virtually the entire range of yaw angles, 0 to 90 deg. Although the yaw parameter is so weak in the atmospheric surface layer that k can be assumed constant at 0.3.

ICE WATER INTERFACE, PREEZING, ICE FOR-MATION, SOIL FREEZING, ICE LENSES, TESTS.

On the basis of observations of freezing fronts and liquid inclusions in liquid-saturated glass beads, a simple technique is described for making these direct observations. The ice-water interface at the freezing front was concave when

viewed from the ice side, because the glass beada were preferentially wetted by the liquid. The size and number of liquid inclusions decreased with distance behind the freezing front. More liquid is trapped by smaller glass beads. The liquid inclusions are probably enriched in soluble impurities. No tendency for pressure buildup or ice lense formation was observed, perhaps because large particles were used. It is very important to extend these observations to other conditions. conditions, especially to smaller particle sizes. MP 1862

FECTS, MATHEMATICAL MODELS.
Thermal measurements of the normal emittance of several disthermanous materials were made at 15.2 C, 4.9 C and -5.6 C. Calculations of the total bemispherical emittance were made from normal emittance and plotted against the optical depth. A comparison of these data with a model proposed by Gardon indicates that at near-ambient temperatures they agree very closely. It has been observed that normal emittance is greater than hemispherical emittance by approx. 5% for both weakly and strongly absorbing materials. This is attributable to phase differences in the multiply reflected internal radiation attempting to exit the specimen throughout steradians. Other radiation properties of the materials, i.e. diffuse transmittance, absorption coefficient, and absorption index were calculated.

CAS, ARTIFICIAL SNOW.

Changes is now crystal characteristics during snowstorms are frequently observed. A continuous record of these changes is required to study the effect of airborne snow on the transmission properties of electromagnetic energy. A continuous snow crystal replicator suitable for this task has been developed and was field-tested at the SNOW II exercise. This replicator, which employs a Fornwar technique for snow crystal replication developed by Schaefer (1956) possesses electronic and mechanical features previously unavailable in other replicators and represents a significant improvement in Fornwar replication technique. A micro-processor controls the operation of the replicator, resulting in improved quality of snow crystal replicas as well as a decrease in data reduction time. This is accomplished by I) regulating the temperature of a heater bar designed to reduce blushing (condensed moisture on the film which obscures the detailed structures of replicated crystals), 2) ensuring uniform thickness of the Fornwar coating by adjusting the flow rate according to film speed, 3) encoding time on the film, and 4) monitoring motion of the film to ensure proper operation of the replicator. A description of this instrument is presented and details of its operation at SNOW II are discussed.

Andreas, E.L., U.S. Army Cold Regions Research and Riginesring Laboratory. Special report, Dec. 1984, SR 84-35, Snow Symposium, 4th, Hanover, NH, Aug. 14-16, 1984. Proceedings, Vol.1, p.161-169, ADB-090 935, 5 refs.

39-2959 SNOW SURFACE TEMPERATURE, HUMIDITY, HYGROMETERS, DEW POINT, SURFACE ROUGHNESS, METEOROLOGICAL DATA, THERMISTORS, ANALYSIS (MATHEMATICS). THERMISTORS, ANALYSIS (MATHEMATICS). Because of the tenuousness of a snow cover, measuring its surface temperature is not easy. The surface is ill-defined and easily disturbed; invasive transducers commonly used for other surfaces may thus be inappropriate for snow. A hygrometric method is described for measuring the snow-surface temperature; the advantages are that it is non-invasive and non-radiative and that it depends only weakly on the surface structure. The key assumption is that air at a now surface is in saturation with the snow; the dew-point temperature of the air is thus T(s), the surface temperature. Consequently, under the right conditions, by measuring the dew-point temperature 10 cm above the surface, we, in effect, measure the surface temperature.

OVERVIEW OF METEOROLOGICAL AND SNOW COVER CHARACTERIZATION AT SNOW-TWO.

TURE DISTRIBUTION, GRAIN SIZE, TESTS.

The performance of military airborne down-look systems, regardless of wavelength, depends upon the recognition of differences between target and background features as viewed through an intervening medium. In cold regions the background may consist partially or entirely of snow cover during winter months. Prediction or evaluation of system performance under such conditions requires detailed characterization of snow cover, meteorological situation and, in some cases, subsurface features such as soil. This paper presents a brief overview of meteorological and snow cover background measurements made at Camp Grayling, Michigan, during SNOW-TWO. Eight independent system tests were supported, each of which required meteorological and/or snow-cover "ground-truth" characterization. Support was provided at four meteorological sites and seven snow cover characterization locations. Methodology is described briefly and a listing given of available data taken by CRREL in support of these tests.

TION.

The attenuation of electromagnetic energy transmitted through falling snow can be determined if sufficient information regarding the physical and optical properties of airborne snow is known. Due to the complex and dynamic nature of falling snow the necessary parameters to predict transmission are often difficult to measure. Therefore it is necessary to carefully evaluate all the snow properties that are measurable in order to identify some ideal set of snow parameters that can be used to adequately model transmission through falling snow. A basic quantitative measurement of falling snow that can be continuously monitored is the mass concentration. Thus an approach to modeling transmistance through snow that can be continuously monitored is the mass concentra-tion. Thus an approach to modeling transmittance through airborne snow using mass concentration as one of the inputs should be thoroughly investigated. This paper explores a potential method of predicting transmittance based on mass concentration measurement, taking into consideration the size and shape of the snow crystals. Although the paper focuses on visible radiation the concepts discussed are also applicable to infrared radiation.

ICS). Measured extinction of light by particles, especially those much larger than the wavelength of the light illuminating them, must be corrected for forward scattered light collected by the detector. Near-forward scattering by arbitrary nonspherical particles is, according to Fraunhofer diffraction theory, more sharply peaked than that by spheres of equal projected area. The difference between scattering by a nonspherical particle and that by an equal-area sphere is greater the more diffusely the particle's projected area is distributed about its centroid. Snowflakes are an example of large stmospheric particles that are often highly nonspherical. Calculations of the forward-scattering correction to extinction by ice needles have been made under the assumption that they can be approximated as randomly oriented prolate spheroids (aspect ratio 10:1). The correction factor can be as much as 20% less than that for equal-area spheres depending on the detector's acceptance angle and the wavelength. Randomly oriented oblate spheroids scatter more nearly like equal-area spheres. equal-area spheres.

TIES.

A new approach was developed for computing the impulse response of a layered material. Our approach is different from other formulations in that we rely on a simple algorithm for polynomial division rather than the usual and more cumbersome matrix schemes. Our model is strictly valid for normally incident plane waves and does not allow for dispersion in a lossy material but we can account for geometrical spreading and believe the technique can be adapted for oblique incidence. The : twantages of our technique are simplicity and the impulse nature of the solution. Consequently, we can compute the band limited response of the layered material through a straightforward convolution of the impulse response with any desired source function. In this paper, we outline the method and discuss examples of radar waves reflected from layers of snow and ice. We suggest the method may be a convenient tool for modelers studying acoustic and electromagnetic reflections from snow and ice cover.

WAVE PROPAGATION, RIVER FLOW, ICE JAMS, DAMS, ELECTRIC POWER, FLOODS, RAIN, MATHEMATICAL MODELS.

RAIN, MATHEMATICAL MODELS.

In this paper we consider long-period, shallow-water waves in rivers that are a consequence of unsteady flow. River waves result from hydroelectric power generation or flow control at a dam, the breach of a dam, the formation or release of an ice jam, and rainfall-runoff processes. The Saint-Venant equations are generally used to describe river waves. This paper is an investigation into areas which are fundamental to river wave modeling. The analysis is based on the concept that river wave behavior is determined by the balance between friction and inertia. The Saint-Venant equations are combined to form a system equation that is written in dimensionless form. The dominant terms of the system equation change with the relative magnitudes of a group of dimensionless soaling parameters that quantify the friction-inertia balance. These scaling parameters are continuous, indicating that the various river wave types and the transitions between them form a spectrum.

ICE STRENGTH, COMPRESSIVE PROPERTIES, STRESS, STRAIN DIAGRAMS, TESTS, MEASUR-ING INSTRUMENTS

ING INSTRUMENTS.

Procedures have been refined for performing constant-strain-rate triaxial tests on ice samples. The equipment is designed such that the confining pressure/axial stress ratio remains constant. Sample axial displacements are measured inside the cell on the sample and outside the cell between the cell and the loading piston. In addition to reviewing the development of the equipment and testing procedures, data are presented to illustrate the problems of using outside displacement measurements. In general, direct axial displacement measurements on the sample are essential to obtain accurate test strain rates and ice moduli. This is particularly true for brittle ice at low temperatures, high strain rates, and high confining pressures.

FROZEN GROUND STRENGTH, SALINE SOILS. SHEAR STRENGTH, DEFORMATION, SOIL FREEZING, CLAY SOILS, SANDS, SEA WATER, TEMPERATURE EFFECTS, TESTS.

TEMPERATURE EFFECTS, TESTS.

Laboratory direct shear strength tests were conducted on sand and clay oil samples as they were freezing. Samples prepared with seawater and distilled water were tested in a modified direct shear box at shear plane temperatures ranging from 0 C to -5 C. The shear strengths of the freezing saline clay and sand samples were observed to esignificantly less than shear strengths of the free water samples. For the clay samples, these shear strength differences could be accounted for principally by the 1.8 C freezing point depression caused by the salts in the sea water, the two shear strength curves nearly paralleling and overlapping each other when plotted versus temperature below freezing. In a similar plot for the sands, the two curves diverge considerably from a common strength at 0 C. It is shown that the shear strength reduction of the saline clay soil is principally the result of increased unfrozen water content. It is postulated that knowledge of unfrozen water content relationships for frozen saline soils will probably allow better predictive capabilities for the shear strength in the freezing zone.

EXPLORATION OF A RIGID ICE MODEL OF FROST HEAVE.

39-3276
FROST HEAVE, GROUND ICE, ICE MODELS, ICE LENSES, FREEZING RATE, ICE GROWTH, MATHEMATICAL MODELS, FROZEN GROUND THERMODYNAMICS.

A numerical model is explored which simulates frost heave in saturated, granular, air-free, solute-free soil. It is based on equations developed from fundamental thermomechanical considerations and previous laboratory investigations. Al-though adequate data are lacking for strict experimental verification of the model, we note that simulations produce an overall course of events together with significant specific features which are familiar from laboratory experience.

Simulated heave histories show proper sensitivities in the shapes and orders of magnitude of output responses and in the relations between crucial factors such as heave rate, 'reezing rate, and overburden.

SIMILARITY SOLUTIONS OF THE CAUCHY PROBLEM OF HORIZONTAL FLOW OF WATER THROUGH POROUS MEDIA FOR EX-PERIMENTAL DETERMINATION OF DIF-

POROUS MATERIALS, WATER FLOW, DIFFU-SION, WATER CONTENT, MATHEMATICAL MODELS, EXPERIMENTATION.

An experimental method for determining diffusivity is studied by using similarity solutions of the Cauchy problem of horizontal flow of water through homogeneous porous media. The theoretical justification of the method is presented by applying a mathematical theorem recently derived by Van Duyn. Some important aspects of data analysis are discussed by using actual experimental data.

The model is run with a daily time step and is forced by interannually varying fields of geostrophic wind and termperature-derived thermodynamic fluxes. The results include documentation of the sensitivities to the source of the thermodynamic forcing data and to the number of thickness levels in the thermodynamic formulation.

The fields of ice velocity and thinkness levels are the sensitivities to the source of the thermodynamic formulation. in the thermodynamic formulation. The fields of ice velocity and thickness show strong seasonal as well as interannual variability. The Pacific gyre is found to be well-developed in spring and autumn but less so in winter and summer. The simulated velocities show no bias but considerable acatter relative to the drift of the Arctic buoys in 1979 and 1980. An analysis of the regional mass budgets shows that the normal seasonal cycle is controlled primarily by the thermodynamic processes but that the thickness anomalies in much of the Arctic are attributable primarily to dynamic processes contribute more strongly to summer anomalies near the ice edge. The tendency for ice anomalies to be advected by the pattern of mean drift is apparent in multisesson lag correlations involving subregions of the Arctic Basin and the peripheral seas. (Auth. mod.)

There would be broad scientific benefit in cetablishing in Alaska an imaging radar receiving station that would collect data from the Buropean Space Agency's Remote Sensing Satellite, ERS-1; this station would acquire imagery of the ice cover from the American territorial waters of the Beaufort, Chukchi, and Bering Seas; this station, in conjunction with similar stations proposed for Kiruna, Sweden, and Prince Albert, Canada, would provide synoptic coverage of nearly the entire Arctic. The value of such coverage to aspects of oceanography, geology, glaciology, and botany is considered.

MP 1885 CONTROLLING RIVER ICE TO ALLEVIATE ICE JAM FLOODING.

Deck, D.S., IAHR International Symposium on Ice, 7th, Hamburg, F.R.G., Aug. 27-31, 1984. Proceedings, Vol.3, [1984], p.69-76, 4 refs. 39-3471

ICE CONTROL, RIVER ICE, ICE JAMS, FLOODS, ICE BOOMS, ICE BREAKUP, ICE COVER THICKNESS, MODELS, COUNTERMEASURES.

NESS, MODELS, COUNTERMEASURES.

Many communities affected by ice jam flooding have accepted the event as unpreventable. Others have approached their problem as one of open channel flow and implemented standard projects such as channel modifications or dikes to combat their flooding. We feel that the best approach is to control the river ice before it poses a problem, by controlling either freeze-up or break-up. This paper addresses our involvement at two areas where ice jam flooding has caused severe economic hardship and loss of life. An ice boom has been used to control the formation of river ice at Oil City, Pennsylvania, and a permanent ice control suructure will be constructed on Cazenovia Creek in West Seneca, New York, to control the river ice during break-up.

ICE EDGE, HEAT LOSS, SEA ICE DISTRIBU-TION, PACK ICE, ANTARCTICA—WEDDELL

SEA.

Surface-level meteorological observations and upper-air soundings in the Weddell Sea provide the first in situ look at conditions over the deep antarctic ice pack in the spring. The surface-level temperature and humidity were relatively high, and both were positively correlated with the northerly component of the 850 mb wind vector as far as 600 km from the ice edge. Since even at its maximum extent, at least 60% of the antarctic ice pack is within 600 km of the open ocean, long-range atmospheric transport of heat and moisture from the ocean must play a key part in antarctic sea ice heat and mass budgets. From one case study, the magnitude of the ocean's role is inferred: at this time of year the total turbulent surface heat loss can be greater under southerly winds than under northerly ones. (Auth.)

ENERGY EXCHANGE OVER ANTARCTIC SEA ICE IN THE SPRING.

SEA ICE, ABLATION, RADIATION BALANCE, HEAT FLUX.

In October and November of 1981, during the U.S.-USSR Weddell Polynya Expedition, we made the first measurements ever of the turbulent and radiative fluxes over the interior pack ice of the southern ocean. The daily averaged, surface-averaged sum of these fluxes—the so-called balance, which comprises the conductive, heat storage, and phase-change

terms—was positive for all but one day during the cruise: the ablation season had begun. Variability in the sum of the turbulent fluxes produced most of the variability in the balance. These turbulent fluxes generally correlated with the geostrophic wind—a northerly wind (in off the cossa) transferring heat to the surface, and a southerly wind resnoving it. (Auth.)

FULL-CYCLE HEATING AND COOLING PROBE METHOD FOR MEASURING THER-MAL CONDUCTIVITY.

McGaw, R., Journal of heat transfer, [1984], No.84-WA/HT-109, 8p., 32 refs.

39-3902

THERMAL CONDUCTIVITY, COOLING, HEAT-ING, THERMAL DIFFUSION, ANALYSIS (MATHEMATICS), TESTS.

(MATHEMATICS), TESTS.

A modification of the traditional probe test procedure is described which incorporates the cooling stage that succeeds each heating stage. The improved procedure enables a second value of thermal conductivity to be determined for each test. A comparison between the two values gives a measure of the experimental error for the test, and provides a means by which physical changes within the test specimen may be detected. If the ambient test temperature of the specimen has altered during a test, the effect on the test values may also be determined through a comparison of the heating-stage and cooling-stage temperatures.

MOCOUPLES, COMPUTER PROGRAMS.

An inexpensive data acquisition/control system is used to control the freeze-thaw cycling and data logging in a new laboratory freezing test. The test imposes two freeze-thaw cycles on four soil samples. The data logger is set up with 3-10 channel multiplexer cards for analog measurement and actuator control. Two of the multiplexer cards are configured for a total of 36 single-ended thermocouple measurements which are accurate to plus or minus 0.1 C. The third multiplexer card is configured with two actuator switches to control the temperatures of two refrigerated circulating baths and with five double-ended channels to read the output of four linear motion DC transformers and one power supply. The data acquisition/control unit is controlled using a HP41CX hand-held calculator and the HP-IL serial interface loop. A thermal printer, tape cassette deck and x-y plotter are used to print out, store and plot the test data. The calculator is programmed with over 30 programs and subroutines to control the temperature, and to reduce, print out, store and plot the test data.

THERMAL CONDUCTIVITY, ENTHALPY, ARTIFICIAL PREEZING, HEAT CAPACITY, PHASE
TRANSFORMATIONS, SOIL FREEZING,
BOUNDARY LAYER, ANALYSIS (MATHEMAT-

ICS).

A new method is presented for solving two-dimensional axisymmetric heat conduction problems with phase change. A strict discontinuity between phases is assumed, and no artificially smoothed enthalpy transition between phases need be introduced. Step changes across phase boundaries in the sensible heat capacity and thermal conductivity are accommodated, when the phase change isotherm cuts arbitrarily across a fixed meah of linear triangular finite elements. Latent heat effects are accounted for through a Dirac delta function in the heat capacity. This is absorbed mathematical function in the course of ordinary Galerkin finite element entities in the course of ordinary Galerkin finite element procedures. Computed results agree well with analytical solutions in the limited cases where they are available, and numerical results in more general cases behave quite reasonably.

40-33
PROST HEAVE, UNFROZEN WATER CONTENT, SOIL WATER, SUPERCOOLING, PRESURE, PHASE TRANSFORMATIONS, SOIL FREEZING, ANALYSIS (MATHEMATICS).

FREBZING, ANALYSIS (MATHEMATICS). The role of the phase equilibrium of water in frost heave was studied for two kinds of soil. The rate of frost heave was the rate of water intake were measured simultaneously under various rates of heat removal. The experimental data revealed a trend common for both soils that the rate of water intake attains its maximum at a certain critical rate of heat removal. The data were analyzed by using equations accurately describing the relation between these rates. The results of the analysis indicate a serious doubt about the validity of phase equilibrium in the system. Alternatively, an assumption was introduced that supercooling occurred between a frost front and an unfrozen part of the soil. It was shown that supercooling could explain the data well under certain conditions.

EXPERIMENTAL STUDY ON FACTORS AF-FECTING WATER MIGRATION IN FROZEN MORIN CLAY.

Xu, X., et al, Ground freezing. Proceedings of the 4th International Symposium on Ground Freezing, Sapporo, Japan, Aug. 5-7, 1985. Edited by S. Kinoshita and M. Fukuda. Rotterdam, A.A. Balkema, 1985, .123-128.

TES1S.

The amount of water migration in an unsaturated frozen soil, morin clay, was determined in horizontally closed soil columns under linear temperature gradients. The temperature at the warm end of the soil column was below its freezing point at the initial water content in order to keep the soil specimen always in the frozen state during testing. The flux of water migration was calculated from the distribution curves of the total water content before and after testing.

Four factors affecting the flux, including temperature, tempera-ture gradient, test duration and the dry density of the soil, were investigated. It was found that the flux is directly proportional to the temperature gradient, is inversely propor-tional to the square root of the test duration, decreases with the decrease in temperature in the power law form, and changes with the dry density. The behavior of water migration in unsaturated, frozen morin clay is something like that in the unsaturated, unfrozen soils.

VOLUME), TESTS.

Tension tests at constant rates were conducted on remolded asturated frozen Fairbanks silt with medium density at 5 C for various machine speeds. It is found that the tensile strength depends strongly upon strain rate and the critical strain rate for ductile-brittle transition was about 1/100s. The peak tensile strength considerably decreases with decreasing strain rate for ductile failure, while it alightly decreases with increasing strain rate for ductile failure, while it alightly decreases with increasing strain rate in the brittle region. The failure strain also varies with strain rate, but the initial tangent modulus is found not to be dependent upon strain rate.

TEMPERATURE, STATISTICAL ANALYSIS.

A small ice island fragment was found in a unique location southwest of Cross Island, Alaska, in April 1983. Investigations were made to determine the thickness, salinity, density, internal temperature, and strength of the ice island co. Measurements were also made which revealed that the ice Measurements were also made which revealed that the ice island had gouged into the seabed when it was driven into shallower waters. Implications of this ice feature to offshore petroleum development are discussed.

APPARENT UNCONFINED COMPRESSIVE STRENGTH OF MULTI-YEAR SEA ICE.

Kovacs, A., International Conference on Port and Ocean Engineering under Arctic Conditions, 8th, Narssarssuaq, Greenland, Sep. 7-14, 1985. Proceedings, Vol. 1, Hörsholm, Denmark, Danish Hydraulic Institute, 1985, p.116-127, 4 refs.

40-270 ICE STRENGTH, SEA ICE, ICE LOADS, COM-

ICE STRENGTH, SEA ICE, ICE LOADS, COM-PRESSIVE PROPERTIES, ICE TEMPERATURE, ICE DENSITY, BRINES, TESTS.

An axial double-ball load test system for determining the apparent unconfined compressive strength of multi-year sea coe was evaluated. The effects of loading ball size, ice temperature, and brine free density on the apparent unconfined compressive strength of the ice were investigated. Axial double-ball load test results are compared with those obtained

from labor intensive conventional unconfined compression tests made on similar density ice. The results from the two testing methods were found to agree very well, indicating that the axial double-ball load test may be used to provide a rapid method for determining an apparent unconfined compressive strength index for ice.

STRUCTURE, ILLE PROCESS.

Sounding of multi-year sea ice, using impulse radar operating in the 30- to 500-MHz frequency band, revealed that the bottom of this ice could not always be detected. This paper discusses the results of a field program aimed at finding out why the bottom of thick multi-year sea ice could not be profiled and at determining the electromagnetic (BM) properties of multi-year sea ice. It was found that the bottom of the ice could not be detected when the ice structure had a high brine content. Because of brine's high conductivity, its volume dominates the loss mechanism in first-year sea ice, and the same was found true for multi-year sea ice. A two-phase dielectric mixing formula, used by the authors for describing the EM properties of first-year sea ice, was modified to include the effects of the gas pockets found in the multi-year sea ice. This three-phase mixture model was found to estimate the BM properties of the multi-year ice studied over the frequency band of of the multi-year ice studied over the frequency band of interest. The latter values were determined by 1) vertical sounding to a subsurface target of known depth and 2) cross-borehole transmission measurements.

DEPTH, GREENLAND SEA.

The physical properties of sea ice in the Fram Strait region of the Greenland Sea were examined during June and July 1984 in conjunction with the MIZEX field program. The properties of the pack ice in the Fram Strait are believed to be representative of ice from many locations within the Arctic Basin since Fram Strait is the major ice outflow region for the Basin. Most of the lice observed and sampled was multi-year. The majority of the first-year ice appeared to have been deformed prior to entering Fram Strait. The properties measured at each sampling site included salinity, temperature, thickness, crystal structure and snow depth. The measured salinities agreed well with those taken during summer at other locations in the Arctic. An important inding was that snow depths on multi-year ice were much larger than those on first-year ice. Finally, the crystal exture analysis indicated that about 75% of the ice consisted of congelation ice with typically columnar type crystal structure. The remaining 25% consisted of granular ice.

STRAIN DIAGRAMS, ICE CRACKS, TEMPERATURE EFFECTS, FRACTURING.

This work presents the results of uniaxial compression tests on freshwater polycrystalline ice. Grain size of the test material ranged from 1.5 to 5 mm, strain rate ranged from 1/1,000,000 to 1/100/s and the temperature was 5 C. The grain size effect emerged clearly as the strain rate increased to 1/100,000/s and persisted to the highest applied strain rates. On average, the stated increase in grain size brought about a decrease in peak stress of approximately 31 percent. The occurrence of the grain size effect coincided with the onset of visible cracking. The strength of the material increased to a maximum at a strain rate of 1/1,000/s, and then dropped somewhat as the strain rate increased further to 1/100/s. Strain at peak stress generally tended to decrease with both increasing grain size and increasing train rate. The results are discussed in terms of the deformation mechanisms which lead to the observed behavior.

WATER FLOW, DELAWARE BAY.

The rediometric and spatial qualities of SPOT simulator and Landsat-3 MSS data are compared as to their shility to distinguish different water masses within Delaware Bay and adjacent wetland areas. The SPOT simulator data contain a greater range of gray level values for all water areas than do the Landsat MSS data. The greater spatial resolution of the SPOT simulator data provides information about small-scale hydrodynamics not available on the Landsat MSS data. Both types of data show a plume of spectrally unique water flowing from Roosevelt Inlet into Delaware Bay. The plume is most visible in SPOT simulator band it (300-590 nm) and Landsat MSS band 4 (500-690 nm). In both bands, the plume appears dark relative to the surrounding Delaware Bay water. Rocent hydrographic surveys characterize the plume as an ebb tidal feature with high concentrations of dissolved and particulate organic matter believed to originate from the adjacent Canary Creek Marsh and Great Marsh. SPOT simulator data are found to delineate water masses with a high degree of separation. Radiometrically degraded SPOT data produce similar results. Landsat-3 MSS data, although useful for delineating water masses, do not produce good separation because of sensor noise.

The complex relative dielectric permittivity of saline ice alabs removed from an artificially grown ice sheet has been measured at 4.75 GHz as a function of temperature. The frequency lies within the range used by other researchers who conducted radiometric tests concurrently on the same ice sheet. The alabs were placed between open waveguide radiators and dielectric properties calculated from the forward scattering coefficient. The results show both real (k²) and imaginary (k²) parts to vary almost in direct proportion to the brine volume. However, the values for k² show more variation, probably due to scattering.

SNOW DENSITY.

Snow cover of both land and ocean (sea ice) areas presents a challenge to remote sensing. On one hand, it acts as a mask over surfaces of interest and part of the remote sensing problem is then to determine whether the snow cover is transparent, opaque, or partially transparent resulting in an ambiguous signature. On the other hand, the properties of the snow cover itself may be of interest, such as depth, anow water equivalent and coverage. Microwave remote sensors in particular have potential to monitor these properties because of their capabilities to penetrate the surface, detect small wetness differences and operate in all weather conditions (Foster, et al., 1985). To realize this potential, it is necessary to understand how snow properties affect remote sensing signatures. Microwave signatures of snow are a function of dielectric constant as well as surface roughness and depth. A primary objective therefore is to determine the relationship between the dielectric constant and environmental parameters, including physical properties of the snow cover and local meteorological variables.

Small-scale experiments were performed to determine sheet ice forces on a conical structure. The experiments were conducted with a 45 deg, upward-breaking conical structure which had diameters of 1.5 m at the waterline and 0.33 m at the top. The surface of the structure was initially amooth; later it was roughened to investigate the effect of surface friction on the ice load. The thickness and the flexural strength of ice sheets were varied, and the tests were conducted at three fixed velocities. The measured ice forces agree well with the forces predicted by plastic limit analysis. There is no effect of velocity on the ice forces for tests conducted for a low coefficient of friction (0.1), whereas some velocity effect on the horizontal ice forces are higher at lower velocities. The horizontal ice forces are higher at lower velocities. The size of the broken ice pieces, determined from a power spectrum analysis of the horizontal ice force records, was found to be about one-third of the characteristic length. Small-scale experiments were performed to determ

SEA. A simulation model for sea ice-induced gouges on the shelf of the Beaufort Sea is developed by assuming that the annual occurrence of new gouges is given by a Poisson distribution, the locations of the gouges are random, and the distribution of gouge depths is specified by an exponential distribution. Once a gouge is formed it is subject to infilling by transport of sediment into the region and by local movement of sodiment along the sea floor. These processes are modeled by assuming a sediment input based on stratigraphic considerations and by calculating bod-load transport using methods from sediment transport theory. It is found that if currents are sufficient to transport sediment, rapid infilling of gouges occurs. In that these threshold currents are small for typical grain sizes on the Beaufort Shelf, this suggests that the gouging record commonly represents only a few tens of years.

SUBSEA PERMAFROST, OCEAN BOTTOM, BOTTOM SEDIMENT, SOIL STRENGTH, ELECTRIC EQUIPMENT, MAPPING, MODELS.

TRIC EQUIPMENT, MAPPING, MODELS.
Geophysical field observations of apparent resistivity using Wenner and dipole-dipole electrode arrays were made at several New England coastal sites The objective was to assess the performance of these systems in detecting resistive seabed features as an indication of their potential for subsea permafrost mapping. Two sites on the Maine coast were used for observations on bedrock below a thin layer of sediments. A seaborne survey was then conducted in New Haven Harbor, Connecticut, at a site where the depth to bedrock below the seabed had been mapped by seismic methods and drilling several years earlier (U.S. Army Corps of Engineers 1981). The data gathered helped to define the range of apparent resistivity values expected in areas of subsea permafrost, the effect of water depth on the quality of a survey, and the vertical and lateral resolution capabilities of the arrays used. Good qualitative agreement between rock depth and resistivity was observed, even with rock deptha up to 50 m below the seabed. Data were also collected in areas where seismic methods had been unable to extract subbottom information due to the gas content of local organic sediments.

ICE SHELVES, GROUNDED ICE, MASS BALANCE, ANTARCTICA—ROSS ICE SHELF.

ANCE, ANTARCTICA—ROSS ICE SHELF.

The identification of a small region of grounded ice in the north-western sector of the Ross Ice Shelf has forced a re-evaluation of the mass-balance calculations carried out by Thomas and Bentley (1978). Those authorn concluded that the Ross Ice Shelf up-stream of Crary Ice Rise was thickening, but they did not take into account the effects on the velocity field of grounded ice which is located near the input gate to their volume element. Reasonable estimates of the despect to which the ice velocity interturent. the input gate to their volume element. Reasonable estimates of the degree to which the ice velocity just up-stream of the grounded ice is diminished indicate that it is no longer possible to conclude that the ice shelf is thickening using Thomas and Bentley's original flow band. Therefore, a new flow band was chosen which was grid east of Thomas and Bentley's band and unaffected by any nearby grounded areas. The mass balance in this flow band was found to be zero within experimental error; a difference exceeding about 0.2 m/s in magnitude between the thickening and bottom freeze-on rates is unlikely. (Auth.)

MP 1920 PREFERENTIAL DETECTION OF SOUND BY PERSONS BURIED UNDER SNOW AVA-LANCHE DEBRIS AS COMPARED TO PER-SONS ON THE OVERLYING SURFACE.

Johnson, J.B., International Snow Science Workshop, Aspen, CO, Oct. 24-27, 1984. Proceedings, Aspen, CO, ISSW Workshop Committee, [1984], p.42-47, 8 refs. 40-801

RESCUE OPERATIONS, AVALANCHE DEPOSITS, DETECTION, SNOW ACOUSTICS, SNOW COVER EFFECT, SOUND WAVES, ATTENUA-

TION.

The preferential detection of sound by a person buried under snow can be explained by the strong attenuation of acoustic waves in snow and the relatively higher level of background acoustic noise that exist for persons above the snow surface as compared to an avalanche burial victim. This noise masks sound transmitted to persons on the snow surface causing a reduction of hearing sensitivity as compared to the burial victim. Additionally, the listening concentration of a buried individual is generally greater than for persons working on the snow surface, increasing their subjective awareness of sound.

ICE CRYSTAL GROWTH, SNOW MELTING,
SNOW COVER, GRAIN SIZE.

SNOW COVER, GRAIN SIZE.

It is necessary to assign terms to snow crystals so that we can refer to them at any time. TCSI (1954) suggested five classes of snow crystals but many important types of crystals were not included. Sommerfield (1969) and then Sommerfield and LaChapelle (1970) suggested a classification based on processes because, if the processes could be correctly identified, information would be provided about both crystal shapes and metamorphic processes. Unfortunately, many of the names used—equitemperature, temperature gradient, and melt-freeze—can misrepresent the processes responsible for generating those shapes. Other terms are suggested here in hopes of correctly describing anow crystals. Only the major categories are dealt with here; a more detailed classification will be published later.

Results from a one-dimensional model that estimates frost heave and thaw settlement are compared to laboratory soil column data. The model is based upon well known equations that describe heat and moisture flow in soils. Processes in freezing or thawing zones are approximated by a lumped isothermal heat budget approach as well as phenomenological equations that account for overburden effects and reduced fluid movement due to ice formation. Laboratory soil column data were obtained for one-dimensional freezing and then thawing of a sit soil. The model results accurately estimate temperature distributions and pore water pressures during thawing.

FROZEN GROUND PHYSICS, SOIL COMPOSITION, GROUND THAWING, UNFROZEN WATER CONTENT, DIELECTRIC PROPERTIES, TEMPERATURE EFFECTS, NUCLEAR MAGNETIC RESONANCE.

The dielectric constant of frozen soils is made up of contributions from each phase—mineral, ice, air and liquid water—in the soil. The apparent dielectric constants of three soils, a kaolinite, Morin clay and Palouse silt-loam, were measured under both thawed and frozen conditions at various temperatures and various water contents using time domain reflectometry (TDR). Nuclear magnetic resonance (NMR) was used to measure the unfrozen water contents of these soils at subfreezing temperatures. The NMR data were used to calculate the volume fractions of the ice and liquid water phases in the TDR experiments. It was found that a mixing model for the apparent dielectric constant of the soil samples assuming spherical sir, ice and minderal inclusions in a water matrix was able to closely fit the TDR data. To obtain the best fit it was necessary to use an average dielectric constant for water somewhat less than that for bulk water. The mixing model can be used for the interpretation of TDR data obtained in the field.

This allows for the measurement of unfrozen water contents using TDR at temperatures just below 0 C, where the liquid water phase makes up a significant portion of the TDR

MOISTURE TRANSFER, FROST REISTANCE. MOISTURE TRANSFER, FROST RESISTANCE. During 1984 and early 1985 frost penetration, frost heave and thaw weakening were monitored on two full-depth test sections at CRREL. The subgrade soil beneath one test section was a lean clay and the subgrade soil beneath the second test section was Hanover silt. Laboratory frost susceptibility tests were conducted for each soil, as were moisture retention curves and curves relating moisture content and unasaturated hydraulic conductivity. Results from the laboratory tests were used with FROSTIB, a coupled heat and mass flow computer model, to simulate performance of the field test sections. FROSTIB had never been applied to a cohesive soil similar to the lean clay. Results from model simulations on both soils agreed well, i.e. within about 15% with field measurements of frost heave and frost penetration with time.

CREEP STRENGTH, STRAIN RATE, TEMPERA-TURE AND UNFROZEN WATER RELATION-SHIP IN FROZEN SOIL.

Fish, A.M., International Symposium on Ground Freezing, 4th, Sapporo, Japan, Aug. 5-7, 1985. Proceedings, Vol.2, [Rotterdam, A.A. Balkema, 1985], p.29-36, 32 refs. 40-661

FROZEN GROUND STRENGTH, SOIL CREEP, STRAINS, FROZEN GROUND TEMPERATURE, UNFROZEN WATER CONTENT, FROZEN GROUND PHYSICS, COMPRESSIVE PROPERTIES, TEMPERATURE EFFECTS, ANALYSIS TIES, TEMPERAT (MATHEMATICS).

(MATHEMATICS).

A relationship was developed between maximum (peak) strength, strain rate, strain, and temperature using data on uniaxial compression of remolded frozen Fairbanks silt obtained in the temperature range from -0.5 to -10 C at constant strain rates (CSR) that varied between 1/100 and 1/1,000,000/s. It is shown that three principal parameters of frozen soil define the magnitude of strength at a given strain rate: the instantaneous strength, the activation energy, and the strain hardening parameter all relate to each other. Their absolute values depend upon temperature and are linked with the simplest physical characteristics of soil and especially the ice and unfrozen water contents. The activation energy with the simplest physical characteristics of soil and especially the ice and unfrozen water contents. The activation energy of frozen soil is presented as a sum of two components: activation energy of the soil skeleton and activation energy of the unfrozen water. The activation energy of frozen soil varied due to the changes of unfrozen water content between 16.6 and 13.2 kcal/mole.

PREDICTION OF UNFROZEN WATER CON-TENTS IN FROZEN SOILS BY A TWO-POINT OR ONE-POINT METHOD.

Xu, X., et al, International Symposium on Ground Freezing, 4th, Sapporo, Japan, Aug. 5-7, 1985. Pro-ceedings, Vol.2, (Rotterdam, A.A. Balkema, 1985), p.83-87, 5 refs. Oliphant, J.L., Tice, A.R.

40-669

FROZEN GROUND, UNFROZEN WATER CON-TENT, DENSITY (MASS/VOLUME), TEMPERATURE EFFECTS.

TURE EFFECTS.

The unfrozen water content in frozen soils, with different initial water content, dry density and molality, was determined by the nuclear magnetic resonance technique. Results show that the unfrozen water content in frozen morin clay changes with the initial water content and the dry density only within a range of three percent of the dry soil weight, and increase with the increase in the molality linearly because of the linear freezing point depression. The curves of the unfrozen water content vs temperature are quite parallel with the change in the initial water content and rotate a little bit counterclockwise with the increase in the dry density. On the basis of the data mentioned above, a two-point method by the measurements of two freezing points at two different initial water contents, and a one-point method by the measurement of the unfrozen water content at 1 C if the initial water content and its freezing point are given, is presented.

Errors of predicting the unfrozen water content are 1-3% on the average for the two-point method and 1% or so for the one-point method.

FROST JACKING FORCES ON H AND PIPE PILES EMBEDDED IN PAIRBANKS SILT.

Johnson, J.B., et al, International Symposium on Ground Freezing, 4th, Sapporo, Japan, Aug. 5-7, 1985. Proceedings, Vol.2, Rotterdam, A.A. Balkema, 1985, p. 125-133, 5 refs. Each, D.C.

URES.
The magnitude and variation of forces and shear stresses, caused by soil frost heaving, for a pipe pile and an H pile were determined as a function of depth along the upper 3 m of the piles for two consecutive winters. The maximum frost heaving forces on the H pile during each winter were 943 kN and 899 kN.

The maximum frost heaving force on the pipe pile was 703 kN.

Maximum local shear stresses for the H pile were 1 MPa and 903 kPa for the pipe pile was 896 kPa.

Maximum local shear stress for the pipe pile was 896 kPa.

Maximum average shear stresses over the two winters were 324 kPa and 427 kPa for the H pile and 324 kPa for the pipe pile.

Maximum heaving forces and shear stresses occurred during periods of maximum cold and soil surface heave magnitude. These were not related to the depth of frost for most of the winter since the soil was frozen completely to the permafrost table.

SHEAR STRENGTH ANISOTROPY IN FROZEN SALINE AND FRESHWATER SOILS.

Chamberlain, E.J., International Symposium on Ground Preezing, 4th, Sapporo, Japan, Aug. 5-7, 1985. Proceedings, Vol.2, Rotterdam, A.A. Balkema, 1985, p.189-194, 2 refs. 40-687

FROZEN GROUND STRENGTH, SHEAR STRENGTH, ANISOTROPY, SALINITY, CLAY SOILS, SANDS, TESTS.

SOILS, SANDS, TESTS.

The shear strength anisotropy of frozen freshwater and seawater clay and sand soils was investigated using the direct shear technique. Samples were sheared at angles of 0, 30, 60 and 90 degrees between the shear and freezing planes. Because of variations in sample density, there was considerable scatter in the data. This scatter and the relationship of the maximum shear strength to the angle between the shear and freezing planes were accounted for by conducting multiple linear regression analysis on empirical equations relating the test variables to the shear strength.

SOIL-WATER POTENTIAL AND UNFROZEN WATER CONTENT AND TEMPERATURE.

PROZEN GROUND TEMPERATURE, NU-CLEAR MAGNETIC RESONANCE, UNFROZEN WATER CONTENT, SOIL WATER, SOIL STRUC-TURE, WATER CONTENT, FREEZING POINTS, SOIL CHEMISTRY, SOIL TEMPERATURE, DEN-SITY (MASS/VOLUME).

SITY (MASS/VOLUME).

Soil-water potential was determined by the extraction method and four factors affecting the soil-water potential, including water content, soil type, dry density and temperature, were investigated. The unfrozen water content of frozen soils was determined by the pulsed nuclear magnetic resonance technique and three factors affecting the unfrozen water content, including initial water content, dry density and salt concentration, were investigated. Results have shown that the soil-water potential in the unsaturated, unfrozen soils decreases both with the decrease in the water content and with the increase in the dispersion of the soil and increases with the increase in the dry density and temperature. The unfrozen water content and the dry density within the initial water content and the dry density whith the initial water content and the dry density whith the increase in the salt concentration.

UNFROZEN WATER CONTENT, FROZEN GROUND PHYSICS, SALINE SOILS, ELECTRI-CAL RESISTIVITY, SOIL CHEMISTRY.

Phase composition curves are presented for a typical saline silt from Lanzhou and compared to some silts from Alaska. The unfrozen water content of the Chinese silt is much higher than the Alaskan silts. This higher amount is

due to the large amount of soluble salts present in the silts from China which are not present in the silts from interior Alesta. When the salts are removed, the unfrozen water contents are then similar for the Chinese and Alaskan silts. We have introduced a technique for correcting the unfrozen water content of partially frozen solid due to high salt concentrations. This correction is possible by calculating the modelity of the unfrozen water at each temperature from a measurement of the electrical conductivity of the extract of a saturated paste.

GREENLAND SEA.
Field investigations of pressure ridge sails have shown that ridge beight is limited by the thickness of the ice that deformed. Sail height and width can be conveniently expressed as functions of the thickness of the ice blocks contained in the ridge. Surface dimensions of the blocks are also related to ice thickness. Ridge height may be determined by the shilty of the parent sheet to support the loading imposed by the ridge or by the type of failure occurring. Some insight into the structure of ridge keels may result from detailed study of the sails. The physical properties of sea ice in the Fram Strait region of the Greenland Sea were examined as part of the MIZEX field program in 1984. The properties measured at each sampling site included salinity, temperature, thickness, crystal structure and snow depth. The measured salinities agreed well with those measured elsewhere in the Arctic during summer. Crystal extructure analysis indicated that about 75% of the ice consisted of columnar type crystal structure. The remaining 25% consisted of granular ice.

SALÍNITY.

Over 500 laboratory tests have recently been completed on ice samples collected from multi-year pressure ridges in the Alaskan Beaufort Sea. Tests were performed in uniaxial constant-terian-rate compression and tension and in confined compression. The tests were conducted at two temperatures, -5 and -20 C, and four strain rates ranging from 1/100 to 1/100,000/s. This discussion summarizes the sample preparation and testing techniques used in the investigation and presents data on the compressive, tension and confined compressive strength of multi-year ridge samples. This information is necessary for designing arctic structures and vessels that must withstand the impact of a multi-year pressure ridge.

A biaxial ice stress sensor has been developed to measure the magnitude and direction of the principal stresses in an ice sheet. Controlled laboratory tests indicate that the sensor has a resolution of 20 kPs and an accuracy of better than 10% under a variety of loading conditions. The sensor has been successfully used to measure thermal ice pressures in lakes and ice loads on a caisson-retained island in the Beaufort Sea.

A simulation model for sea ice-induced gouges on the shelves of the polar seas is developed by assuming that the annual occurrence of new gouges is given by a Poisson distribution, the locations of the gouges are random, and the distribution of gouge depths is specified by an exponential distribution. Once a gouge is formed it is infilled by assuming a sediment input based on stratigraphic considerations and by calculating bed-load transport using methods from sediment transport theory. If currents are sufficient to transport sediment, rapid infilling of gouges occurs. In that these threshold currents are small for typical grain sizes, this suggests that the gouging record commonly represents only a few tens of years.

TEMPERATURE DEPENDENCE OF THE EQUI-LIBRIUM FORM OF ICE. Colbeck, S.C., Journal of crystal growth, Sep. 1985,

72(3), p.726-732, 25 refs. 40-981 ICE CRYSTAL GROWTH, ICE CRYSTAL STRUC-

TURE, SNOW CRYSTAL STRUCTURE, TEM-PERATURE EFFECTS, PLATES, SURFACE ROUGHNESS, EXPERIMENTATION.

ROUGHNESS, EXPERIMENTATION. Individual crystals are grown under controlled conditions at temperatures between -0.6 and -20 C at rates as low as 1/10,000,000. The transition between the kinetic growth form and the equilibrium form is clearly distinguished at temperatures between -2 and -10 C where the equilibrium form is a well-rounded plate with an aspect ratio of about 2.5. At temperatures below -11 C the equilibrium form is a hexagonal prism of about the same aspect ratio. This transition coincides with the rapid increase in surface roughening on the prism faces at temperatures above -10 C. The equilibrium form is a fully rounded particle just below C although we had expected the fully rounded particle to prevail down to at least -5 C. Purthermore, there are unresolved differences between these experimental results and observations of crystals from the seasonal snow cover where particles are fully rounded at slow growth rates and low temperatures.

ICE JAM FLOOD PREVENTION MEASURES: AMOILLE RIVER AT HARDWICK, VER-

MONT, USA.
Calkins, D.J., International Conference on the Hydraulics of Floods and Flood control, 2nd, Cambridge, England, Sep. 24-26, 1985. Proceedings, Cranfield, Bedford, England, BHRA, The Fluid Engineering Centre, 1985, p.149-168, 4 refs.

ICE CONTROL, ICE JAMS, RIVER ICE, FLOODS, WATER LEVEL, TOPOGRAPHIC EFFECTS, COUNTERMEASURES.

Prevention of ico-induced flooding is very difficult, but the impact can be minimized if the winter ice regime can be altered. The Lamoille River at Hardwick, Vermont, is a steep, shallow stream during non-ice periods. Under ice jam conditions stage increases of 1-2 m above the elevation of the floodplain have been measured. Several experimental measures have been implemented to minimize the ice jam flood levels; their performance was evaluated for the winter of 1983-84.

Piping systems represent the major portion of the total cost of most district heating applications and constitute a barrier to their widespread implementation. This paper presents a methodology for least-cost design of these systems under realistic conditions of varying load. Cost-effective design of piping for district heating and cooling applications requires careful consideration of the various components of the owning and operating costs. These costs are included in the formulation of an optimization problem to determine the minimum cost design on a yearly cycle basis.

LAMATION, CHEMICAL ANALYSIS.

A rational procedure for estimating nitrogen removal in facultative wastewater stabilization ponds has been developed and validated.

The procedure, based on first order plug flow kinetics is dependent on pH, temperature and residence time.

The model was developed from extensive data obtained at four facultative ponds in various parts of the US. and was validated with independent data from five pond systems in the US. and Canada. The procedure should be useful whenever system design criteria require nitrogen removal or nitrification. It should be particularly heighful for the pond component of land treatment systems when nitrogen is the limiting design parameter.

ANALYSIS.
Rapid infiltration is a reliable and cost effective technique for wastewater treatment. Over 300 municipal systems are in successful use in the United States. A few of the recently constructed systems have not satisfied all design expectations, particularly with respect to the amount of wastewater that can infiltrate within the time allowed. Correction of these problems often requires additional construction and increases costs but the cumulative effect is also to raise general concerns within the profession regarding the suitability and applicability of the basic concept. An analysis of the failures, and some of the problem systems was conducted and this paper will describe the results.

THEORY OF NATURAL CONVECTION IN SNOW.

Powers, D., et al, Journal of geophysical research, Oct. 20, 1985, 90(D6), p.10,641-10,649, 31 refs. O'Neill, K., Colbeck, S.C.

THEORIFS.
Buoyancy-driven flows of air in snow are modeled including the effects of phase change and inclination. Phase change between water vapor and ice is important because of latent heat terms in the energy equation. Upper boundaries of the snow are taken as either permeable or impermeable, with temperature or heat flux specified at the lower boundary. When the ratio of thermal to mass diffusivity is greater than 1, phase change intensifies convection. When this ratio is less than 1, phase change damps convection. The effects of permeable top and uniform heat flux bottom boundary conditions on beat transfer are quantified and described as linear functions of Ra/Ra(cr), where Ra is the Rayleigh number and or refers to the critical value for the onset of Benard convection. The slope of each function depends only on the thermal boundary condition at the lower boundary. If a snow cover is inclined, Rayleigh convection occurs

for any nonzero Rayleigh number. Velocity profiles for flows in inclined layers with permeable tops are derived, and it is found that velocity is proportional to Ra sin plit, where phi is the angle of inclination from the horizontal. The numerical results for different boundary conditions compare reasonably well with experimental results from the literature.

FORWARD-SCATTERING CORRECTED EX-TINCTION BY NONSPHERICAL PARTICLES. Bohren, C.F., et al. Applied optics, Apr. 1, 1985, 24(7) p.1023-1029, For another source see 39-2966. refs. Koh, G.

SNOWFLAKES, LIGHT SCATTERING, SNOW CRYSTAL STRUCTURE, PARTICLES, ICE NEE-DLES, ANALYSIS (MATHEMATICS).

DLES, ANALYSIS (MATHEMATICS).

Measured extinction of light by particles, especially those larger than the wavelength of the light illuminating them, must be corrected for forward-scattered light collected by the detector. Near-forward scattering by arbitrary nonspherical particles is, according to Fraunhofer diffraction theory, more sharply peaked than that by spheres of equal projected area. The difference between scattering by a nonspherical particle and that by an equal-area sphere is greater the more diffracely the particle's projected area is distributed about its centroid. Snowlakes are an example of large atmospheric particles that are often highly nonspherical Calculations of the forward-scattering correction to extinction by ice needles have been made under the assumption that they can be approximated as randomly oriented prolate apheroids (aspect ratio 10:1). The correction factor can be as much as 20% less than that for equal-area spheres depending on the detector's acceptance angle and the wavelength. Randomly oriented oblate-spheroids scatter more nearly like equal-area spheres. area spheres.

Lawson, D.E. 40-1222

ICE RAPTING, GLACIAL DEPOSITS, SEDIMENTATION, MORAINES, STRATIGRAPHY, FOS-SILS, ORIGIN, GLACIER FLOW.

SILS, ORIGIN, GLACIER FLOW.

Pebble fabric studies on ice-rafted diamictons have been limited to general observations, with authors noting preferences toward vertical, random, or horizontal orientations. To clarify such observations, pebble fabric data were collected from a fossiliferous diamicton of late Pleistocene age located on Whidbey Island, Washington. The ice-rafted origin of this unit is supported by several independent characteristics including in situ macrofauna and microfauna, conformity with subsequeous lithofacies containing dropstones, lower bulk densities and higher void ratios than associated tills, soft sediment deformation structures suggestive of iceberg dumping, textural gradations, and facies relationships. Analysis using the eigenvalue method indicates that ice-rafted fabrics are nearly random with little consistency of vector orientations the eigenvalue method indicates that ice-rafted fabrics are nearly random with little consistency of vector orientations between sites and without any relationship to the probable direction of glacial flow. The weak fabric is mainly the product of settling through the water column and impact with, or penetration of, the bed. Samples that possess a weak preferred long axis orientation with a low angle of dip, including those from laminated muds, can best be explained by the intermittent effects of bottom currents, a resistant substrate at the time of deposition and postexplained by the intermittent effects of bottom currents, areaistant substrate at the time of deposition and post-depositional flowage. Comparisons of pebble fabrics from basal tills, recent sediment flow deposits, and basal, debrished in the constraint control of the constraint control of the constraint control of the control of the

SNOW COVER EFFECT, SNOW ACOUSTICS, SOUND TRANSMISSION, NOISE (SOUND).

SOUND TRANSMISSION, NOISE (SOUND). Pactors which control the audibility within and outside deposition of sound by persons buried under avalanche debris as compared to persons on the overlying snow surface. Strong attenuation of acoustic waves in snow and the small acoustic impedance differences between snow and air are responsible for the strong absorption and transmission-loss characteristics are independent of the direction of propagation of acoustic signals through the snow. The preferential detection of sound by a person buried under snow can be explained by the relatively higher level of background acoustic noise that exists for persons above the snow surface as compared to an avalanche buriel victim. This noise masks sound transmitted to persons on the snow surface, causing a reduction of hearing sensitivity as compared

to the burial victim. Additionally, the listening concentra-tion of a buried individual is generally greater than for persons working on the snow surface, increasing their subjective awareness of sound. (Auth.)

TURE MEASUREMENT.

Image contrast enhancement sometimes complicates image understanding. A scene that consists of slightly dissimilar target and background emittances may not be readily identifiable without image enhancement. Even if the emittance differential can be sharply contrasted, those image surface patterns that convey subsurface thermal information may not be visible because of the wide dynamic range that must be accommodated by the thermal imaging system. This paper describes how emittance complicates the interpretation of thermal images. High and low emittance values affect the logic required for understanding thermal scenes. Thermal scenes containing emittance differentials are easier to interpret if there is a large contrast between the object and the background.

RADIOMETRY, OPTICAL PROPERTIES, IN-FRARED PHOTOGRAPHY, TEMPERATURE MEASUREMENT, ABSORPTION, MATERIALS. MEASUREMENT, ABSORPTION, MATERIALS. Thermal (2.0 to 5.6 micron) measurements of the normal emissivity of several diathermanous materials having alightly different refractive indices were made at 15.2 C. 4.9 C, and -5.6 C. Calculations of the total hemispherical emissivity were made from normal emissivity and plotted against the optical depth. A comparison of these data with a model proposed by R. Gardon J. Am. Ceram. Soc. 39(8), 278 (1956) indicates that at near-ambient temperatures they agree very closely. This comparison presumes that the narrow range of refractive indices about n=1.5 associated with these specimens would not preclude them from being treated as having a value of 1.5.

DIFFUSION.

By comparing experimental measurements of the hydraulic conductivity and the effective self-diffusivity of water in porous media, a channeling parameter, c, is defined. This parameter measures the degree of division of flow paths in the media, but does not depend on the tortuosity of the paths or surface effects on the viscosity of the water. Values of c are obtained for Na-asturated montmorillonites containing from 0.82 to 7.7 g of water per g of clay and for Fairbanks silt containing from 0.135 to 0.23 g of water per g of silt. Values for the montmorillonites remain relatively close to the theoretically predicted value of 1/3 at all water contents, indicating maximally divided flow paths. Values for the silt vary from 100 to over 2000, indicating highly channeled flow.

CONTENT, FREEZING RATE, TESTS.

Sixteen specimens made of Morin Clay with a saturation percentage of 86% were subjected to freezing tests in open system fed by distilled water, NaCl solution, CaCl(2) solution and Na(2)SO(4) solution respectively. Before freezing test, specimens were homogeneous in water content but heterogeneous in chemical composition with a vertical concentration gradient. After freezing test, both water content and the dominant-anilon content in frozen part of the soil samples increase; this means that not only moisture but also ions were migrating toward the freezing zone during tests.

TENSILE STRENGTH OF PROZEN SILT. Zhu, Y., Journal of glaciology and geocryology, Mar. 1986, 8(1), p.15-28, 9 refs., In Chinese with English RIIMMETV Carbee, D.L. 40-4635

FROZEN GROUND STRENGTH, TENSILE PROPERTIES, STRAIN TESTS, SEDIMENTS, SOIL COMPACTION, DENSITY (MASS/-VOLUME), TEMPERATURE EFFECTS.

Constant strain-rate tension tests were conducted on remolded saturated frozen Pairbanks slit at various temperatures, strain rates and densities. It is found that the critical strain rate of the ductile-brittle transition does not depend upon temperature, but varies with density. It has a value of 0.01/s for the silt with medium density and 0.0005/s for low density. The peak tensile strength considerably decreases with decreasing strain rate for ductile failure, while it slightly decreases with increasing strain rate for brittle fracture. The failure strain remains almost the same for temperatures lower than about -2C, but it varies with density and strain rate. The initial tangent modulus is found not to depend upon strain rate, but increases with decreasing temperature and density. Constant strain-rate tension tests were conducted on re

MP 1972 ICE BLOCK STABILITY.

Daly, S.F., Water for resource development, Proceedings of the ASCE Hydraulics Division Specialty Conference, edited by D.L. Schreiber, New York, American Society of Civil Engineers, 1984, p.544-548, 5 refs.

RIVER ICE, ICE FLOES, ICE PRESSURE.

RIVER ICE, ICE FLORS, ICE PRESSURB.

In this paper a simple formulation of the forces acting on an ice block in contact with an intact ice cover is presented. Underturning of the ice block is the assumed mechanism by which the block is swept under the ice cover. The data can be divided into two separate cases, a shallow water case and a deep water case. The conditions of instability for each case are determined empirically. The resultant prediction of the velocity at which the block is swept under the cover reproduces the data very well over the entire trange of nondimensional ice block thicknesses. The "nospill" condition used in earlier formulations is not required.

Locating buried utilities for repair, servicing or prevention of damage is often necessary when excavation is to be conducted in a particular area. The most widely used methods for detection of buried facilities are magnetic induction, magnetometry, and radiofrequency tracking. Downward-looking radar units designed specifically for utility location are in the development stages. Comparative field tests of eight locators were conducted at West Point and Newburgh, New York, over various types of buried utilities including iron and steel pipe, cable, vitreous tile pipe and plastic pipe.

AIRBORNES-NOW CONCENTRATION MEASURING EQUIPMENT.
Lacombe, J., U.S. Army Cold Regions Research and Engineering Laboratory. Special report, June 1982, 82-17, Snow Symposium, 1st, Hanover, NH, Aug. 1981. Proceedings, p.17-46, ADB-091 442, 12 refs.

SNOWFALL, SNOWFLAKES, FALLING BODIES, MEASURING INSTRUMENTS, VISIBILITY, AIRBORNE EQUIPMENT, ACCURACY,

A brief introduction to the function of the Airborne-Snow Concentration Measuring Equipment (ASCME) and its useful-ness for characterizing the winter environment is given. The deficiencies of alternative systems are identified. ASCME deficiencies of alternative systems are identified. ASCME hardware and basic system operation are described in detail. The governing design equation and choice of design parameters are discussed, along with estimates of system accuracy. Evidence of ASCME's satisfactory performance during its inaugural operation at SNOW-ONE is presented and design improvements to be incorporated and used during SNOW ONE-A are mentioned. Snowfall rate and airborne-snow concentration data are also compared, showing a weak correlation between the two parameters at low concentration levels.

SNOWSTORMS.

A survey of the surface pressure systems, weather fronts, and air masses that influenced northern Vermont during the periods of snowfall in January and February 1981 was conducted. Vertical profiles of the temperature and moisture, and observations of the falling snow crystals made at the SNOW-ONE site were also retrieved for the same time period. This information was used to conduct a study on associations between meteorological conditions and observed snow crystal characteristics. Examples of the results obtained from the various nowall events that occurred during the field test period are presented. This study was conducted with the ultimate objective of associating large-scale weather patterns with the on-site frozen particle characterization measurements, and the data obtained concurrently by the electro-optical sensor systems.

GEOMETRY AND PERMITTIVITY OF SNOW. Colbeck, S.C., U.S. Army Cold Regions Research and Bugineering Laboratory. Special report, June 1982, 82-17, Snow Symposium, 1st, Hanover, NH, Aug. 1981. Proceedings, p.113-131, ADB-091 442, 37

40-1933 SNOW PHYSICS, ELECTROMAGNETIC PROPERTIES, SNOW ELECTRICAL PROPERTIES, SNOW CRYSTAL STRUCTURE, POROSITY, SNOW WATER CONTENT, UNFROZEN WATER CONTENT.

WATER CONTENT.

The geometry and porosity of dry snow varies widely depending on the history of conditions. The permittivity of dry snow increases with increasing ice content but is not greatly affected by the shapes of the ice particles. In wet snow the permittivity increases with liquid content and the geometry is very important. However, the liquid-like layer has little effect on permittivity. The permittivity is described using Polder and van Santeen's mixing formulae and approximations of the geometries at high and low liquid contents. It is shown that the common assumption of liquid shells over

ice spheres is both physically incorrect and leads to large

STRUMENTS, SETTLEMENT (STRUCTURAL). Theoretical and experiment studies of time-dependent deformation and failure of columnar-grained ice are presented. Laboratory uniaxial compression tests at constant and steadily increasing stresses were accompanied by simultaneous recording of acoustic emissions. Strength criteria and constitutive equations were established, describing grain disintegration, microcrack imitiation and acoustic emission dynamics during creep, and their relationship to the rheological properties of ice. The rheological properties of ice were studied under laboratory and field conditions using a pressuremeter, leading to the development of an in situ method for determining the mechanical properties of ice taking into account the time factor. The results of the studies were applied in analyses of settlements of foundations on high-ice-content soils and ground ice. Based on the comparison of experimental data with calculated settlements, it is shown that the characteristics of ice used in the analysis can be determined either from laboratory tests or in situ, by means of a pressuremeter.

MP 1989 VIBRATION ANALYSIS OF THE YAMA-CHICHE LIGHTPIER.

Haynes, F.D., International Modal Analysis Conference, 4th, Los Angeles, CA, Feb. 3-6, 1986, Proceedings. Vol.1, Schenectady, N.Y., Union College, 1986, ings. Vol. 1, Schen-p. 238-241, 11 refs.

40-1900

SOIL FREEZING, FROST HEAVE, SOIL COM-PACTION, FROST RESISTANCE, SOIL PRES-SURE, TEMPERATURE GRADIENTS, TESTS.

SURE, TEMPERATURE GRADIENTS, TESTS.

The response of soils to freezing has been assessed in terms of frost heave, and the heaving pressure developed when the specimen is restrained. As both techniques have been suggested for assessing freet susceptibility, it was considered essential to determine the influence of the test conditions on the soil response. This investigation was concerned with specimen preparation, specimen size, and freezing procedure. The test material consisted of an artificially produced matrix, into which controlled amounts of coarse aggregate could be blended. This reduced the likelihood of variation in the results because of random changes in the test materials. The results clearly demonstrated the sensitivity of both heave and heaving pressure to the test conditions. When modified or new test methods are being formulated, it is essential to consider the influence of such factors, particularly when making comparisons between different testing techniques. Such modifications may also require changes in the particular criteria used to assess frost susceptibility.

FIELD OBSERVATIONS OF ELECTROMAGNETIC PULSE PROPAGATION IN DIELECTRIC SLABS.

Arcone, S.A., Geophysics, Oct. 1984, 49(10), p.1763-1773, 15 refs.

ELECTROMAGNETIC PROPERTIES, ICE COVER EFFECT, WAVE PROPAGATION, DIE-LECTRIC PROPERTIES, ICE SHEETS, PRO-FILES, VELOCITY, REFLECTION, REFRAC-TION.

TION.

The propagation of electromagnetic pulses in naturally occurring dielectric surface layers has been examined. Pulse duration used in field experiments reported here has been on the order of nanoseconds with pulse bandwidths in the high VHF to low UHF band. The layers were sheets of fresh water ice and granite at thicknesses ranging between 4 and 4 m. Both transverse electric (TE) and transverse magnetic (TM) modes were attempted but only the TE propagation could be interpreted. Analog recordings of wide-angle reflection and refraction (WARR) profiles were taken and recorded in a continuous graphic display. The displays allowed easy identification of phase fronts thereby facilitating study of the dispersion of the pulses. The phase allowed easy identification of phase fronts thereby facilitating study of the dispersion of the pulses. The phase and group velocities of the wave-group packets agree well with the velocities predicted from dispersion curves derived from the modal waveguide equation. In one case the Airy phase of wave-packet propagation occurred. The best measure of the dielectric constant of the layer was the frequency of the air wave.

ICE COVER STRENGTH, MILITARY OPERA-TION, PENETRATION TESTS, EXPLOSIVES, ICE DEFORMATION.

ICE DEFORMATION.

Shaped charges fired from air into ice give holes of typical form for cohesive solids. There are only a few reported results from test shots in ice, but supplementary data can be obtained by adjusting the results from tests in ice-bounded soil in accordance with target density. Present indications are that charges with narrow angle cones (appr. 45 deg) can penetrate about 16 cone diameters, giving a hole diameter near mid-depth of about 1/3 of the cone diameter. Charges with wide-angle cones (60-90 deg) might penetrate about 12 cone diameters, giving a hole diameter near mid-depth of about 2/3 cone diameters. So far, we have no data for shaped charges fired into ice under water.

ICE MECHANICS.
Information on routine snow and ice survey programs in Finland, Iceland, Norway, Sweden, Canada and the United States is juxtaposed in this paper.

Standard methods of ice and snow measurement and practical alternative methods are described with information on reporting procedures and data storage. In each case, points of contact are provided for those seeking data on floating snow and ice. The purpose of the paper is to improve the flow of information between those responsible for winter lake and river programs in circumpolar countries.

AIRPORTS, PAVEMENTS, FREEZE THAW CY-CLES, CRACKING (FRACTURING), DAMAGE, CLIMATIC FACTORS, DESIGN.

CLIMATIC FACTORS, DESIGN.
In early fall 1984, USACRREL conducted a study of airport pavements in cold regions of the United States. The most common pavement problems were associated with non-traffic related phenomena and include (1) pre-existing cracks reflecting through asphalt concrete overlays (in two years or less), (2) thermal cracking, and (3) longitudinal cracking (at a construction joint). Most of the airports experienced (1) water pumping up through cracks and joints in the pavements during spring thaw, or (2) additional roughness due to differential frost heave in the winter, or both problems. Many airport managers reported that debris was generated at cracks during the winter and spring. Several airports experienced problems with lighting in the winter and spring. Many pavement problems can be traced to the evolutionary history of general aviation airports and the lack of consideration for site drainage.

MP 2003 LESSONS LEARNED FROM EXAMINATION OF MEMBRANE ROOFS IN ALASKA.

SION, THERMAL EFFECTS.

During 1984 and 1985 airborne infrared roof moisture surveys were conducted of membrane roofs at army installations in Alaska. Many of these roofs were also visually inspected and cored to verify infrared findings. Numerous areas of wet insulation were found but often they were small enough and the surrounding roofing system was in good enough condition to warrant removal and replacement of just the wet areas. Essentially all moisture entered from the exterior through flaws in the membrane and flashings. The lack of problems from internal moisture indicates that current vapor retarders, even though imperfect, are adequate. Some "cold regions" appurtenances such as membrane control joints, and insulation breather vents appear to do more harm than good. The protected membrane (upside-down) roofing system is well suited to Alaska but some problems have occurred when the membrane lacks alope to drain. Low-strength concrete pavers used for roof ballast have been deteriorated by freeze-thaw action.

ICE CONTROL, RIVER ICE, ICE JAMS, ICE CONDITIONS, ICE BOOMS, DRIFT, ICE MECHANICS, FLOODING, COUNTERMEASURES. CHANICS, FLOODING, COUNTERMEASURES. The upper one-third of the Delaware River is characterized by a steep gradient with a general riffle/pool sequence. Due to seasonal low flows, a considerable volume of ice is generated and transported throughout the winter months. During February 1981 a catastrophic breakup ice jam occurred along a reach of the Delaware River near Port Jervis, NY, causing \$1.45. million in damages. In February 1982 another breakup ice jam occurred at the same location, causing much concern but minimal flooding and damages. These events prompted the Philadelphia District, U.S. Army Corps of Engineers, to conduct an investigation of the Upper Delaware River to determine if some form of ice control structure could be implemented in order to reduce ice jam-induced flooding. This paper focuses on the field investigations and analyses performed by the U.S. Army Cold Regions Research and Engineering Laboratory for the Philadelphia District during the period 1983-1985. The study included both on site and remote monitoring of ice conditions and hydraulic analysis of several ice control structure alternatives.

EXPERIMENTS ON THERMAL CONVECTION IN SNOW.

PELLERS.

To compare results of icing studies conducted in wind tunnels with natural icing conditions, a series of rotor icing studies were made on top of Mt. Washington, New Hampshire. The results indicated that considerable differences cust between the two under conditions of similar liquid water content and temperature.

The west-to-dry growth transition temperature, for instance, with comparable temperature and liquid water content, may be more than 10 C higher under natural conditions than in wind tunnel studies.

The possible cause of such discrepancies was found to be the vapor saturation existing in most laboratory experiments. The transition existing in most laboratory experiments. The transition experiment of ice accretion measured in natural fog on board an aircraft agreed better with the results of the Mt. Washington study.

When subjected to a sustained temperature gradient in the presence of moisture in laboratory wetting tests, urethan and expanded polystyrene roof insulations accumulate enough moisture to significantly reduce their insulating ability. moisture to significantly reduce their insulating ability. Extruded polystyrene is quite resistant to moisture in such tests. But the vapor drive is not as great in actual roofs and it may reverse direction, thereby seasonally drying the insulation. To determine how well the laboratory tests could predict the wetting rate of insulation in actual protected membrane roofs, extruded and expanded polystyrene and urethane insulations were installed in a protected membrane roof in Hanover, N.H. After three years of exposure, little moisture had accumulated in the extruded polystyrene and it still retained essentially all of its initial insulating ability.

BRITTLENESS, PENETRATION TESTS.
Exploratory tests of ice penetration were made by driving small blunt cyfinders into semi-infinite ice at normal incidence. Three types of laboratory tests were made: (1) drop-weight impact (impact speed 1.4-3.1 m/s), (2) high-speed ballistic penetration (impact speed 83-434 m/s), (3) deep penetration at low speed (0.42-4.23 m/s). Penetration by indenters and projectiles could be characterized by the energetics of the process, with little variation of specific energy as penetration speed changed by orders of magnitude. Por biunt penetrators entering ice at -5 C, specific energy was typically in the range 1.5-15 MJ/cu m. Low speed tests provided data on penetration force (and energy) as a function of displacement. The test results were compared with other published laboratory data, and with field tests results for bigger projectiles. bigger projectiles.

MP 2015 STATISTICS OF COARSENING IN WATER-SATURATED SNOW.

SNOW WATER CONTENT, PARTICLE SIZE DIS-TRIBUTION, SLUSH, WET SNOW, SATURA-TION, STATISTICAL ANALYSIS.

TION, STATISTICAL ANALYSIS.

The particle size distributions in water-saturated snow are distinctly log-normal at all times. The rate of increase of the average volume decreases somewhat with time. Both of these conclusions are contrary to the LSW theory, which should apply to this system. Also, the particles are distinctly spheroidal, probably prolate. These discrepancies might be explained by extending the LSW theory to nonspherical particles with interparticle contacts. When normalized to the mean the distribution is invariant with only the mean changing with time.

Gould, L.D., Burch, W.B. 40-2694

ICE CORES, ICE SAMPLING, EQUIPMENT, FREEZING, WATER TEMPERATURE, COMPRESSIVE PROPERTIES.

PRESSIVE PROPERTIES.

This short note describes the equipment and procedures developed to mount end caps on ice-core specimens. The system typically achieves end-plane parallelism within 0.5 micron/mm of specimen diameter (i.e. a total indicator runnut of 0.002 in for a 4.0 in diameter specimen). The essential elements of the system are a holder and an alignment fixture. The holder firmly grips the ice core about its circumference by the compression of two series of O-rings. The alignment fixture clamps the holder to align the ice core procisely with the end caps. To bond the ice to the end cap we form a layer of 0 C water on the end cap; the water freeze immediately upon contact with the ice and forms a strong intimate bond. To date, this system has been used to install phenolic end caps on 101.6

mm diameter cores and aluminum end caps on 76.2 mm diameter cores of saline ice. A somewhat better tolerance was obtained with the aluminum caps, due primarily to the geometric stability of that material under the prevailing conditions. These specimens have been successfully tested in uniaxial and triaxial compression, and with appropriate end caps the system should be suitable for preparing tension specimens as well.

DAMAGE.

The ice forces generated during continuous crushing of an ice sheet against a cylindrical vertical structure vary with time, according to the resistance offered by ice as it fails and clears from the path of the structure. Small-scale experiments were performed to measure the ice forces by pushing rigid cylindrical structures of different diameters at different velocities through an ice sheet. The dominant frequency, was determined from the frequency spectra of the force records. The characteristic frequency plot with respect to the velocity-to-thickness ratio reveals a linear relationship, which implies that the average length of the damage zone is proportional to the ice thickness. On the basis of the data presented here, the average length of the damage zone is about one-third of the ice thickness.

MP 2019 WAVELENGTH-DEPENDENT EXTINCTION BY

FALLING SNOW. Koh, G., Cold regions science and technology, Peb. 1986, 12(1), p.51-55, 9 refs.

SNOWFALL, LIGHT TRANSMISSION, INFRA-RED RADIATION, LIGHT SCATTERING, VISI-BILITY, WAVE PROPAGATION, PARTICLES.

BILITY, WAVE PROPAGATION, PARTICLES.

Wavelength-dependent extinction in the visible and infrared regions of the electromagnetic spectrum has been observed during studies of transmission through falling snow. The wavelength dependence was particularly noticeable during periods of light snowfall. Particles comparable in size to the wavelengths were also present during these periods. These particles were assumed to be water droplets, and their extinction cross-sections were determined from Miscattering calculations. The calculations suggest that these particles were responsible for the wavelength-dependent extinction observed during snowfall.

ELECTROMAGNETIC MEASUREMENTS OF MULTI-YEAR SEA ICE USING IMPULSE RA-

SEA ICE, ICE BOTTOM SURFACE, ELECTRO-MAGNETIC PROPERTIES, ICE STRUCTURE, BRINES, AIR ENTRAINMENT, RADIO ECHO SOUNDING, DIELECTRIC PROPERTIES, ICE PHYSICS, RADAR ECHOES.

PHYSICS, RADAR ECHOES.
Sounding of multi-year sea ice, using impulse radar operating in the 80- to 500-MHz frequency band, has revealed that the bottom of this ice cannot always be detected. This paper discusses a field program aimed at finding out why this is so, and at determining the electromagnetic (EM) properties of multi-year sea ice. It was found that the bottom of the ice could not be detected when the ice structure had a high brine content. Because of brine's high conductivity, brine volume dominates the loss mechanism in first-year sea ice, and the same was found true for multi-year ice. A two-phase dislectric mixing formula, used by the authors to describe the EM properties of first-year sea ice, was modified to include the effects of the gas pockets found in the multi-year ice. This three-phase mixture model was found to estimate the EM properties of the multiyear ice studied over the frequency band of interest.

MENTAL PROTECTION.

A literature search indicated that natural freezing may have detrimental effects at uncontrolled hazardous waste sites in the cold-dominated areas because of frost action on buried materials and ion movement in soils. Natural and artificial freezing, however, can be used beneficially to concentrate effluents, and to dewater studges, contaminated sediment and soils. The process of artificial ground freezing can also be used as an alternative to temporarily immobilize contaminant transport and potentially for decontamination of soils, sediments and aludges. A cost and economic analysis procedure was developed and used to evaluate ground freezing.

POTENTIAL USE OF ARTIFICIAL GROUND FREEZING FOR CONTAMINANT IMMOBILI-ZATION.

Jenkins, T.F. 40-2951

WASTE TREATMENT, ARTIFICIAL FREEZING, SOIL FREEZING, FREEZE THAW CYCLES, SOIL POLLUTION, COUNTERMEASURES, WASTE DISPOSAL, ENVIRONMENTAL PROTECTION. DISPOSAL, ENVIRONMENTAL PROTECTION.

This paper summarizes a preliminary investigation of the potential use of ground freezing technology for contaminant immobilization. Preezing and thawing were found to significantly decrease the volume of soil sturry and increase the permeability of soils. Frozen metal-contaminated soils eliminated metal leaching to groundwater under the site. Freezing and thawing soils contaminated with moderately volatile organics significantly reduced the soil concentrations of these organics. Freezing the soil from the bottom apparently enhanced upward movement of the organics to the soil surface where losses occurred by volatilization. The amount lost depended on the mobility of the specific volatile component and was as high as 90% for chloroform, betaene and toluene and as low as 45% for tetrachloroethylene. Input to groundwater during freezing and thawing of these organics was much less than the unfrozen (control) treatment. Artificial ground freezing for decontamination of soils and for immobilization of contaminants is now being tested on a larger scale

FRIGERATION.
Ground freezing for hazardous waste containment is an alternative to the traditional and expensive slurry wall or grout curtain barrier technologies. The parameters quantified in this analysis of it include thermal properties, refrigeration line specing, equipment mobilization and freezing time constraints. The economics of the process is discussed based on the Poetsch method for ground freezing. Vertical drill holes with concentric refrigeration lines are spaced along the desired freezing line. A header or manifold system provides coolant to an interior pipe, with the return line being the outer casing. A self-contained refrigeration system pumps coolant around the freezing loop. Temperature-measuring instrumentation is appropriately placed to monitor the progress of the freeze front.

ICE ISLANDS, GROUNDED ICE, ICE SALINITY, ICE TEMPERATURE, ICE DENSITY, SHEAR STRENGTH, ICE LOADS, ARTIFICIAL ISLANDS, TESTS, OFFSHORE STRUCTURES.

LANUS, IESIS, OPPSHORE STRUCTURES. Salinity, temperature, density, and sheer strength tests were performed on the confined flooded ice in the 1976-77 East Harrison Bay grounded ice island. The constructed ice had a mean salinity of 13.8 ppt, a mean density of 877 kg/cu m, and a mean horizontal shear strength of 0.74 MPa. The shearing resistance of the constructed ice and the sliding resistance of the constructed ice and the sliding resistance of the constructed ice and the sufficient to prevent the island from being pushed off location by ice movement.

MP 2033 FREE AND FORCED CONVECTION HEAT TRANSFER IN WATER OVER A MELTING HORIZONTAL ICE SHEET.

Lunardini, V.J., International Offshore Mechanics and Arctic Engineering (OMAE) Symposium, 5th, Tokyo, Apr. 13-18, 1986. Proceedings, Vol.4, New York, American Society of Mechanical Engineers, 1986, p.227-236, 24 refs. 40-3142

ICE MELTING, HEAT TRANSFER, WATER FLOW, ICE TEMPERATURE, ICE SHEETS, WATER TEMPERATURE, CONVECTION.

WATER TEMPERATURE, CONVECTION.

Experiments were conducted to study the melting of a horizontal ice aheet with a flow of water above it. The experiments were conducted in a refrigerated flume 35 m long with a cross section of 1.2 x 1.2 m. Water depth, temperature, and velocity were varied as well as the temperature and initial surface profile of the ice sheet. It was found that the heat transfer regimes consisted of forced turbulent flow at high Reynolds numbers with a transition to free convection heat transfer at lower Reynolds numbers. There was no convincing evidence of a forced laminar regime.

MP 2034

HEAT TRANSFER CHARACTERISTICS OF THERMOSYPHONS WITH INCLINED EVAPORATOR SECTIONS.

EVALUES, F.D., et al, International Offshore Mechanics and Arctic Engineering (OMAE) Symposium, 5th, Tokyo, Apr. 13-18, 1986. Proceedings, Vol.4, New York, American Society of Mechanical Engineers, 1986, p.285-292, 21 refs.

VELOCITY, AIR TEMPERATURE, TESTS,
THAW DEPTH.

THAW DEPTH.

Laboratory tests were conducted on two commercial fullsize thermosyphons, one charged with carbon dioxide and
one with ammonia. The test variables were evaporator
inclinational angle, wind speed and ambient air temperature.
Empirical expressions are presented for thermal conductance
as a function of these test variables. The laboratory test
results were used in finite element simulations run on an
IBM-PC microcomputer to study three design parameters
influencing the thermal regime below slab-on-grade foundations
in a permaftost location. Insulation thickness, thermosyphon conductance and vertical placement were varied in
these simulations. The effect of these variables on the
maximum depth of thaw are given.

CONFINED COMPRESSIVE STRENGTH OF MULTI-YEAR PRESSURE RIDGE SEA ICE

Cox, G.F.N., et al, International Offshore Mechanics and Arctic Engineering (OMAE) Symposium, 5th, Tokyo, Apr. 13-18, 1986. Proceedings, Vol.4, New York, American Society of Mechanical Engineers, 1986, p.365-373, 17 refs.

FECTS, PRESSURE, STRESSES.

FECTS, PRESSURE, STRESSES.

Fity-five constant-strain-rate triaxial tests were performed on vertically oriented multi-year pressure ridge samples from the Beaufort Sea. The tests were performed on a closed-loop electrohydraulic testing machine at two nominel strain rates (1/100,000 and 1/1,000 per sec) and two temperatures (-20 and -5 C). In all of the tests the confining pressure was ramped in constant proportion to the applied axial stress. This paper summarizes the sample preparation and testing techniques used in this investigation and presents date on the confined compressive strength and fellure strain of the ice.

Uniaxial data are also included for comparison.

MP 2036 SOME EFFECTS OF FRICTION ON ICE FORCES AGAINST VERTICAL STRUCTURES. Kato, K., et al, International Offshore Mechanics and RAIO, E., et al. International Offshore Mechanics and Arctic Engineering (OMAE) Symposium, 5th, Tokyo, Apr. 13-18, 1986. Proceedings, Vol.4, New York, American Society of Mechanical Engineers, 1984, p.528-533, 17 refs. Sodhi, D.S., Haynes, D.

40-318 40-318 ICE FRICTION, OFFSHORE STRUCTURES, ICE BREAKING, ICE SOLID IN-TERFACE, ICE CONDITIONS.

TERPACE, ICE CONDITIONS.

The contributions of frictional forces to the overall ice forces exerted against sloping structures have been studied before, but their effect on the ice forces against vertical structures has not yet been studied. In this paper, the influence of frictional resistance on the crushing and buckling failure loads of ice sheets against flat, vertical structures is discussed. Small-scale experiments were conducted to compare experimental results to those from theoretical formulations. The main conclusions of this study are: a) the orunking ice forces increase with increasing coefficient of friction between ice and structure, and b) the buckling failure loads also increase due to changes in boundary condition induced by increasing frictional resistance at the ice/structure interface.

MP 2037 IMPACT ICE FORCE AND PRESSURE: AN EX-

IMPACT ICE FORCE AND PRESSURE: AN EX-PERIMENTAL STUDY WITH UREA ICE. Sodhi, D.S., et al, International Offishore Mechanics and Arctic Engineering (OMAE) Symposium, 5th, Tokyo, Apr. 13-18, 1986. Proceedings, Vol.4, New York, American Society of Mechanical Engineers, 1986, p.569-576, 10 refs. Morris, C.E.

PRESSIVE PROPERTIES.

An experimental study was undertaken of the total force and local pressure generated during the impact of a vertical cylindrical structure against the edge of an ice sheet. The test structure was an instrumented cylindrical pile that protruddunder a massive ram suspended from two crances in the form of a bifliar pendulum. Measurements were made of impact velocity, total ice force, and pressure at a point on the pile. The dependence of normalized maximum ice forces with respect to aspect ratio has the same trend as that for the crushing failure of an ice sheet against a vertical structure. The results of this study indicate that the instantaneous maximum pressure can be an order of magnitude higher than the unconfined compressive strength of ice.

MP 2035

MP 2038 ICE FLOE DISTRIBUTION IN THE WAKE OF A SIMPLE WEDGE.

SIMPLE WEDGE.

Tatinclaux, J.C., International Offshore Mechanics and Arctic Engineering (OMAE) Symposium, 5th, Tokyo, Apr. 13-18, 1986. Proceedings, Vol.4, New York, American Society of Mechanical Engineers, 1986, p.622-629, 6 refs.

40-3198

ICE BREAKING, ICE WEDGES, ICE FLOES, SEA ICE DISTRIBUTION, ICEBREAKERS, ICE STRENGTH, ICE COVER THICKNESS, ICE MODELS, ICE CONDITIONS, TESTS.

Tests in level ice on an idealized icebreaker bow in the shape of a simple wedge were conducted and the fice size distribution in its wake was observed. The ice fice lengthy and ice fice area were found to follow log-normal probability distributions defined by the length average and area average, and corresponding standard deviations.

MP 2034 CONDENSATION CONTROL IN LOW-SLOPE ROOPS.

Tobiasson, W., Moisture Control in Buildings: Workshop proceedings, Sep. 25-26, 1984. Edited by E. Bales and H. Trechael, Washington, D.C., Building Thermal Envelope Coordinating Council, [1985], p.47-59. 47 refa

BUILDINGS, DAMAGE, CONSTRUCTION
MATERIALS, MAINTENANCE.

MATERIALS, MAINTENANCE.

Excessive moisture can damage wood, metal, and concrete roof decks, cause bituminous membranes to wrinkle, shrink, spiti, delaminate and blister and significantly reduce the insulation ability of most roof insulations. Low-sloped wood-frame roofs with below-deck insulation have encountered a significant number of condensation problems. Few such problems occur for compact membrane roofs without intervening air spaces. Air leakage control probably explains the difference. However, serious condensation problems occur in some compact membrane roofs, particularly in cold regions. For most roofs, upward vapor flow in warm weather. Thus, the objective is to install air-vapor retarders to roduce wings wetting to an acceptable level. Ventilation of the space between the membrane and the retarder is also practiced.

ROOF MOISTURE SURVEYS: YESTERDAY,
TODAY AND TOMORROW.

Tobiasson, W., et al, International Symposium on Roofing Technology, 1985. Proceedings. A decade of change and future trends in roofing, Chicago, IL, National Roofing Contractors Association, [1985], p.438-443 + figs., 45 refs.

ROOFS, MOISTURE DETECTION, THERMAL INSULATION, CONDENSATION, MEASURING INSTRUMENTS.

INSTRITON, CONDENSATION, MEASURING INSTRITON, CONDENSATION, MEASURING INSTRITON, CONDENSATION, MEASURING INSTRITON.

Roof moisture surveys are conducted with nuclear meters, capacitance meters take readings at the spots on the roof with points spaced from 5 to 10 feet apart. Nuclear meters sense the amount of hydrogen in the roofing system at each spot. Since most dry roofs contain hydrocarbons, they do not give zero readings. When water also is present on the roof, nuclear readings increase since water is part hydrogen. Capacitance meters create an alternating current electrical field in the roofing system below. When there is water in the roof, its dielectric properties change and the reading on the capacitance meter increases. Capacitance meters do not "see" deeply (a few inches at most) into the roofing system. An infrared scanner senses the temperature of the surface of the roof. Wet insulation changes the ability of the roofing system to store and conduct thermal energy, thereby causing changes in its surface temperature which the infrared scanner can detect. Instead of a mater reading, the infrared results are presented as shades of brightness on a video monitor. This qualitative visual image provides information about every square inch of the roof, but the information is more subjective than the numbers generated at grid points by nuclear or capacitance meters.

VAPOR DRIVE MAPS OF THE U.S.A. Tobiasson, W., et al, Hanover, NH, Cold Regions Research and Engineering Laboratory, (1986), 7p. + graphs, 9 refs. Presented at the ASHRAE/DOE/B-TECC Conference "Thermal Perforamnce of the Exterior Envelopes of Buildings III", Clearwater Beach, FL. Dec. 1985.

THERMAL INSULATION, CONDENSATION, MOISTURE, WATER VAPOR, MAPS, BUILDINGS, METEOROLOGICAL FACTORS, DESIGN CRITERIA, SEASONAL VARIATIONS

CRITERIA, SEASONAL VARIATIONS.
The thermal performance of most insulations used in building envelopes will be seriously degraded if the insulation becomes wet. Problematic moisture can come from within the building envelope. Guidance on when to use "sir-retarders" needs improvement. As a step in this direction, weather records have been analyzed and two series of maps have been made that relate the relative humidity within a building to the vapor pressure gradients across the building envelope. Each map in the first series is for a specific ratio of cold weather wetting potential to warm weather drying potential. Each map in the second series is for a specific cold weather wetting potential. To determine which map in each series is most appropriate to use as design criteria, we are requesting guidance from the building profession.

HEAT FLOW SENSORS ON WALLS—WHAT CAN WE LEARN.

Flanders, S.N., American Society for Testing and Materials. Special technical testing publication, 1985, No.885, p.140-149, 10 refs.

THERMAL INSULATION, WALLS, HEAT TRANSFER, HEAT FLUX, HEAT LOSS, BUILD-INGS, ACCURACY, THERMAL CONDUCTIVI-

TY.
This paper addresses the validity of employing heat flow sensors (HFSs) on the indoor surfaces of building walls to determine thermal characteristics. It also reports on the results obtained in the field. Some of the factors affecting HFS measurement accuracy (together with a likely percentage standard deviation attributable to that factor) are as follows: (a) the conductivities of HFS and its surroundings (3%), (b) convection mode changing over the sensor, causing a +21% bias (26%), (c) the mismatch of HFS absorptive with the surroundings (6%), and (d) thermal contact of the HFS with the surface (1%). A propagation-of-errors analysis indicetes that the resulting standard deviation of an HFS measurement would be approximately 10% of the mean of the measurements.

MEASURING INSTRUMENTS.

The U.S. Army Cold Regions Research and Engineering Laboratory has recently acquired an instrumented vehicle for the measurement of forces at the tire/surface material interface. The CRREL instrumented vehicle (CIV) is equipped with moment-compensated triaxial load cells mounted in the front wheel assemblies. Forces are measured in the vertical, longitudinal (in the direction of motion) and side directions. In addition, accurate wheel and vehicle speeds and rear axle torque and speed are measured. Modifications to the vehicle (to facilitate the performance of traction and motion resistance tests) include four lock-out type hubs to allow front-, rear- or four-wheel drive and a dual brake system for front-, rear- or four-wheel drive and a dual brake system for front, rear- or four-wheel braking. A mini-computer-based data acquisition system is installed in the whicle to control data collection and for data processing, analysis and display. Discussion of the vehicle includes its operation and use for the evaluation of the tire performance and surface material properties of motion resistance and

REFLECTION, MEASURING INSTRUMENTS.

A large-diameter open-ended coaxial waveguide has been interfaced with a commercially available time domain reflectometry (TDR) unit for field measurements of the dielectric properties of frozen and thawed soils and ice. A core barrel developed by the U.S. Army Cold Regions Research and Engineering Laboratory (CRREL) and modified for use in frozen soil was used to auger an annular slot around which the waveguide fits. Time domain traces of waveforms reflected from the sample-air interface and from a metal short are recorded in the field and later analyzed to give complex dielectric permittivity between 0.05 and 1.0 GHz.

REVERSED-PHASE HIGH-PERFORMANCE LIQUID CHROMATOGRAPHIC DETERMINA-TION OF NITROORGANICS IN MUNITIONS WASTEWATER.

Concentrations of HMX, RDX, TNT, and 2,4-DNT are determined in munitions wastewater. Aqueous samples are diluted with an equal volume of 76/24 (v/v) methanol-acetronitrile, filtered through a 0.4 microgram polycarbonate membrane, and analyzed by reversed-phase HPLC using an LC-8 column with 50/38/12 (v/v/v) water-methanol-acetonitrile. The method provided linear calibration curves to at least several hundred micrograms per liter. Detection limits were conservatively estimated to be 26, 22, 14, and 10 microgram/L for HMX, RDX, TNT, and 2,4-DNT, respectively, with corresponding standard deviations of 250 microgram/L. At higher concentrations, the percent relative standard deviation values were approximately 2% for HMX and RDX and 4% for TNT and DNT. A ruggedness test involving the major manipulative steps in the procedure indicated that consistent rer ults required glass sample containers, preconditioning of filters, and careful maintenance of sample-to-organic solvent ratio. The method was tested with munition wastewater from several Army ammunition plants and found to perform adequately for load and pack wastewaters, wastewater from HMX/RDX manufacture, and contaminated groundwater. WASTE TREATMENT, WATER TREATMENT, WATER POLLUTION, CHEMICAL ANALYSIS, WATER CHEMISTRY, COUNTERMEASURES,

A reversed-phase HPLC method for the determination of nitroorganic compounds (DNT, TNT, RDX, HMX) in munitions wastewaters was evaluated in a collaborative study. Nine laboratories analyzed four aqueous matrices, including groundwater and treated wastewater, which were spiked with the analytes at levels from 30 to 600 microgram/L. Recoveries of analytes were similar regardless of matrix: DNT and RDX being recovered quantitatively, and TNT and HMX ahowing losses of about 5%. Intralaboratory precisions, based on the average of duplicate determinations, were less than 15 microgram/L, which corresponds to 9% relative standard deviation at the average concentration examined. Interlaboratory precisions were at most 50% larger than intalaboratory values. Valid statistical analysis required rejection of about 10% of the data set as outliers. The retionale for applying a variety of statistical evaluations is discussed.

ROCKS, CRACK PROPAGATION, ELASTIC PROPERTIES, TENSILE PROPERTIES, FRACTURING, STRENGTH, TESTS.

TURING, STRENGTH, TESTS.
Laboratory tests confirm the accuracy of the compliance equations for wedge-loaded, linearly elastic, double cantilever beam test specimens used for the measurement of fracture energy G(I) but show that there are significant discrepancies with theory in tests on rock specimens of the same design. The dependence of the compliance on the length of the crack in the test specimen is not correctly predicted by theory for the experiments done on rock. The axial load applied to the arms of the double cantilever beam as a result of wedge loading reduces Young's modulus by as much as 44% and decreases the measured elastic anisotropy of specimens of granite. The experiments show that useful measurements of G(I) can be made on rock provided that the Young's modulus used in the determination of G(I) is measured on the same specimen under the same conditions of loading as are used in the fracture experiments.

Equations are developed that can be used to determine the amount of gas present in sea ice from measurements of the bulk ice density, salinity, and temperature in the temperature range of -2 to -30 C. Conversely these relationships can be used to give the density of sea ice as a function of its temperature and salinity, considering both the presence of gas and of solid salts in the ice. Equations are also given that allow the calculation of the gas and brine volumes in the ice at temperatures other than that at which the bulk density was determined. (Auth.)

A new technique for measuring the speed of radar waves in polar ice sheets was developed to investigate a previously reported disagreement between the permittivities of laboratory and glacier ice. The technique involves lowering a cylindrical radar target to several carefully measured depths in a borehole and measuring the travel time of a radar wave transmitted from a surface radar unit to the target in the borehole. The experiment was performed at Dome C, East Antarctica, and Dye-3, Greenland, and useable data were collected for target depths between 200 and 800m. After computing the range to the target along a straight ray path and after correcting the travel time for delays in in the radar receiver, the velocities determined from these experiments were found to be in good agreement with evelocities predicted by Robin's empirical formula. The apparent discrepancy between the permittivity of glacier ice, as measured using the radar wide-angle reflection method, and laboratory ice now seems to be due in large part to signal delay in the radar receiver that was ignored in earlier experiments. ICE SHELVES, FLOW RATE, RADAR ECHOES, ICE COVER THICKNESS, ANTARCTICA—ROSS ICE SHELF, ANTARCTICA—SIPLE COAST, AN-TARCTICA—CRARY ICE RISE.

TARCTICA—CRARY ICE RISE.

Variations in the amplitude of radar echoes from the bottom of the grid western half of the Ross Ice Shelf have been analyzed. Contrary to the results of a similar analysis performed for the grid eastern sector of the ice shelf, bands of low signal strength downstream from both Crary Ice Rise and the Siple Coast do not correlate with modern flow lines. The difference in direction between the radar bands downstream of Crary Ice Rise and the present velocity vectors and the absence of of a comparable trend farther east suggest to us that the grounding line around Crary Ice Rise retreated within the last 1000 years. This hypothesis is reinforced by the observation of several domes and hollows in ice thickness downstream of Crary Ice Rise which are similar to a hollow now located in the wake of the ice rise and a dome of its eastern flank. We interpret this as evidence for a rapid increase in flow around the ice rise. Similar but less detailed evidence found downstream of the Siple Coast suggests that there was a regional retreat of the West Antarctic grounding line. (Auth.)

MODIFIED THEORY OF BOTTOM CRE-VASSES USED AS A MEANS FOR MEASURING THE BUTTRESSING EFFECT OF ICE SHELVES ON INLAND ICE SHEETS.

Jezek, K.C., Journal of geophysical research, Mar. 10, 1984, 89(B3), p.1925-1931, 20 refs.

38-2914
ICE SHELVES, CREVASSES, FLOATING ICE, ICE MECHANICS, ANTARCTICA—ROSS ICE

Bottom crevasses are fractures that extend upward into floating ice shelves. They form when seawater penetrates the base of the ice shelf and ruptures the ice up to the level at which englacial stresses equal the stress of the seawater. For a freely floating ice shelf, the penetrating level of closely spaced crevases is estimated at about half the ice thickness

h; for an isolated crevasse the level is about pi h/4. However, an analysis of the heights and locations of bottom crevasses in the Ross ice Shelf shows that none of the crevasses approach the predicted limits, perhaps because the existing theory does not include the back stress which is present in bounded ice shelves. By reformulating the theory to include a back stress term, back stress can be evaluated experimentally from radar measurements of crevasse height and ice thickness. The magnitude of back stress (2 bars in the grid northwest corner of the ice shelf) suggests the ice shelf is playing an important role in buttreasing the inland ice sheet. (Auth.)

This paper describes the equipment and methodology used to determine the resilient properties of granular soils that exhibit thaw-weakening behavior. Such soils suffer a significant loss in stiffness as the result of freezing and thawing and subsequently experience an increase in stiffness during a recovery phase. The recovery phase results from gradual desaturation of the thawed soil and is characterized by an increase in the soil moisture tension level. We have developed a means to simulate this freeze-thaw-recovery process in the laboratory that calls for testing specimens several times at soil moisture tension levels corresponding to field observations.

movement surveys are no more accurate than the benchmarks used as reference. In northern areas, frost action can cause substantial vertical movement of benchmarks. Benchmarks can also subside or shift in wetland and coastal areas. Various benchmark designs and installation procedures reduce or eliminate movement, but information on the designs and procedures is widely scattered and not available to Corps of Engineers Districts in one report. This paper gives the preliminary results of a synthesis of existing information compiled from surveys of Crops of Engineers Districts and Divisions, U.S. and Canadian government agencies and private industry and from a literature review. A matrix for selecting benchmarks appropriate for various climatic and soil conditions will be prepared from the synthesized information. This matrix and a description of the procedures required for installing various types of benchmarks will be available in September 1985. Techniques used for topographic, hydrographic and structural movement surveys are no more accurate than the benchmarks

WHITTARY OPERATION, TANKS (COMBAT VEHICLES), COLD WEATHER OPERATION, METEOROLOGICAL FACTORS, LASERS, INSTRUMENTS, WINTER, VISIBILITY, OPTICAL PROPERTIES, ELECTRICAL PROPERTIES, SNOWFALL

This paper describes the SNOW-III-WEST experiment and a related study conducted in the Federal Republic of Germany that was designed to increase the understanding of the effects of winter weather on the performance of electro-optical sensor that we designed to lictues the innertaneous of the weather on the performance of electro-optical sensor systems in main battle tanks. SNOW-III-WEST was conducted at Camp Grayling, Michigan, during December 1984 and January 1985. Its objectives were to document the performance of the M1 tank EO sensor suits in winter and gather data from threat vehicle EO sensors and M1 tank developmental sensors for use in developing system capability comparisons. To secomplish this, an M1 tank gunners primary sight (GPS) was positioned to view and range to vehicular targets at distances out to 1600 m. The GPS contains a day sight, nigh sight and laser rangefinder. Other U.S. and threat EO systems were co-located with the GPS. Day and sight sight imagery through the device optics was recorded using video equipment while simultaneous target observations by the sight operator were documented. Detailed measurements were made to characterise important target scene and environmental factors. These included:
meteorological, airborne-snow, scene illumination, and stmospheric transmission measurements, as well as inherent and messurouguess, arrorme-mow, scene numanation, and atmospheric transmission measurements, as well as inherent and apparent visible and infrared target/background signature measurements. PM Sanoke's personnel response and evaluation system for target obscursion (PRESTO) was used to document the sight operator's target detection responses.

MP 2074 EFFECIS OF SNOW ON VEHICLE-GENERAT-ED SEISMIC SIGNATURES.

Albert, D.G., Sensor Technology Symposium, 4th, Apr. 26-28, 1983. Report. Vol.1: Unclassified papers, U.S. Army Engineer Waterways Experiment Station, Vicksburg, MS, Environmental Laboratory, July 1984, p.83-109, 9 refs. 40-3531

SNOW COVER EFFECT, MILITARY OPERA-TION, SEISMIC SURVEYS, ATTENUATION, ACOUSTICS, SEASONAL VARIATIONS, VEHI-

CLES.

Vehicle-generated seismograms recorded under summer and winter conditions at Fort Devens, Massachusetts, are analyzed and compared. The data were recorded using three-component geophones loosted just beneath the ground surface and microphones mounted on tripode 0.3 m tail. Winter data were recorded with a 0.7-m-thick snow cover present at the test site. The 14-track PM field tapes were digitized in the laboratory at a sampling rate of 500 Hz is proparation for filtering and spectral analysis. The filtering effect of the snow cover on the seismic data is striking. Because the acoustic-to-eismic coupled energy is attenuated by the snow, the appearance and frequency content of the recorded ground motion is changed dramatically. Automatic vehicle classification algorithms will have to account for these effects classification algorithms will have to account for the if they are to operate successfully in the presence

FROZEN PRECIPITATION AND CONCUR-RENTLY OBSERVED METEOROLOGICAL CONDITIONS.

Bilello, M.A., [1985], 11p., Presented at the 42nd Meeting of the Bastern Snow Conference, Montreal, Canada, June 1985. 8 refs. 40-3532

SNOWFALL, PRECIPITATION (METEOROLOGY), METEOROLOGICAL DATA, STATISTICAL ANALYSIS, FREEZING, AIR TEMPERATURE, HUMIDITY, WIND VELOCITY, FOG, VISIBILITY, DIURNAL VARIATIONS.

This study evaluates statistical data for two or more meteorological parameters, recorded concurrently during the winter. The analysis considers only freezing forms of precipitation, placed into seven categories, and correlated with simultaneously observed atmospheric conditions, such as temperature, humidity and wind speed. Computer tabulated data from 11 years of winter weather for München/Riem, West Germany, were obtained for the investigation. Typical results are: 1) the variations in absolute humidity values that can be expected during periode of fog or ground fog at different air temperatures, 2) the likelihood that freezing rain or freezing drizzle will occur least frequently between 1200 and 1700 hours, and 3) the diurnal and monthly air temperatures, relative humidity and examples of the unusual and interesting environmental knowledge that can be gained from available climatic records; similar investigations can be conducted for other sites that have long-term weather records in computer-based files.

HEAT TRANSFER, DIURNAL VARIATIONS. The phenomenon of deterioration of ice, particularly of floating ice on rivers and lakes, is commonly observed during the spring period. The result of the deterioration is a porous, honeycomb-like structure, generally of low strength, and the greatly reduced strength contributes to the timing of ice break-up as well as significantly reducing the load-carrying capacity of the ice cover. A combined radiation-conduction heat transfer analysis is presented that predicts the diurnal strength variations associated with low surface albedo and internal melting. The results are compared with field data.

MP 2001 MODELING OF ICE DISCHARGE IN RIVER MODELS.

Calkins, D.J., Conference on Frontiers in Hydraulic Engineering, Cambridge, MA, Aug. 9-12, 1983. Pro-ceedings. Edited by H.T. Shen, New York, American coedings. Edited by H.T. Shen, New York, America Society of Civil Engineers, 1983, p.285-290, 7 refs. 40-3565

RIVER FLOW, RIVER ICE, ICE MECHANICS, DRIFT, ICE MODELS, HEAT TRANSPER, EX-PERIMENTATION, TEMPERATURE EFFECTS, HYDRAULICS, FREEZEUP.

HYDRAULICS, FREEZEUP.

A thermal modeling criterion for the ice discharge in refrigerated physical river models is presented along with laboratory results. Ice production was evaluated for freshwater and for 0.3% and 1% ures concentrations in water. Discharges of 0.0056 and 0.0094 cu m/s were run in the model river at air temperatures of 5, 10 and 15C. Preliminary results show that as the concentration of ures in the water is increased, the model ice outflow increases. The measured ice discharge at river outlet and the ice accumulation on the riverbed are both linearly related to the air-water temperature difference. The ice accumulation rate on the riverbed are both linearly related to the air-water temperature difference. The ice accumulation rate on the riverbed was also found to be a linear function of time. The freshwater flow had a greater bed accumulation rate than ures-doped solutions. A slight increase in model ice production was noted for the higher water flow rates. Proper acaling of the ice discharge through a model reach may require relaxing the heat transfer coefficient scaling law because sufficient ice cannot be generated in the river, and ice must be introduced at the inlet of the model. By changing the urea concentration in the water or using a separate ice production flume, a wide range of values for the input of model ice discharge can be selected.

DYNAMIC FRICTION OF BOBSLED RUN-NERS ON ICE.

METAL ICE FRICTION, SLEDS, ICE SURFACE, ICE FRICTION, ICE DETERIORATION, DYNAMIC LOADS, MODELS, EXPERIMENTATION, STATISTICAL ANALYSIS.

TION, STATISTICAL ANALYSIS.

The challenge we have been presented with, to perfect the runners of the U.S. Bobsied Team's aled for the 1988 Winter Olympics in Calgary, requires an understanding of the experimentation performed by other researchers, the conclusions reached, and the limitations of their findings. Most of the ice friction studies to date have been made under more or less idealized conditions. Thus, in the highly dynamic situation of a bobsied or a skier sliding on a rough ice surface, a variety of unknown and disregarded factors may contribute greatly to the friction phenomena. For instance, one of the previous studies addressed the mechanical destruction of the ice surface, though carving or melting a track in the ice could account for most of the frictional energy loss. This paper describes the results of a preliminary study performed using a model sled.

OHIO RIVER MAIN STEM STUDY: THE ROLE OF GEOGRAPHIC INFORMATION SYSTEMS AND REMOTE SENSING IN FLOOD DAMAGE ASSESSMENTS.

RAPHY.

The simulated SPOT data acquired from aircraft over the study site had several radiometric characteristics which would not be encountered in the nadir-looking satellite observations. These differential scene brightness features were removed from the data. The corrected data were used in two studies to assess their information content for water quality assessment and land cover classification. Both studies indicate that the SPOT data are comparable to high altitude color-infrared serial photography in digital form. The implication for land cover mapping is that techniques developed for LANDSAT MSS will need to be modified to allow for interactive user input and the use of textural and contextual features in automatic digital classification. The results of the water quality analysis point to the potential of the SPOT data for assessing the presence of materials in the light-interactive zone of the water column.

YEGETATION, REMOTE SENSING, SPECTROS-COPY, PHOTOINTERPRETATION, MAPPING, CLASSIFICATIONS, AGRICULTURE, UNITED STATES—MINNESOTA—LAC QUI PARLE.
SPOT High Resolution Visible (HRV) simulated data were obtained over Lac qui Parle, Minnesota, to determine their usefulness for mapping wildlife habitat categories associated with Corps projects. Ground truth data were available from photointerpreted wildlife habitat unit maps and the agricultural crop inventory prepared for the summer of 1983. A geometric correction could not be applied to the data was assessed. The sample size of 512 x 512 pixels was suscessful in discriminating wheat and affalfa and other uniformly colored areas, but pasture and corn could not be separated. Also, we were not successful in separation of grasslands and legumes. Our results indicated that the 20-m HRV data can be used to photointerpret wildlife habitat using the false color image, but a digital classification cannot be performed. To obtain a habitat map using the HRV data would require a multitemporal analysis.

STRENGTH.

The U.S. Army Cold Regions Research and Engineering Laboratory has studied the sea ice environment of the Beaufort Sea for many years. Offshore development is now proceeding beyond the barrier islands and many of these studies have relevance to the planned activities. Sea ice presents a formidable hazard to the design and construction of production platforms and sea floor pipelines. CRREL investigations have addressed a number of the problems associated with these activities and remote sensing has played a major role in some of these studies. Specific efforts at CRREL have addressed the measurement of ice motion, the distribution and morphology of pressure ridges and shore ice pile-ups, ice conditions and thickness, the determination of ice strength, ice crystal structure, and the modeling of ice dynamics and thermodynamics.

MP 2087 ICE BANDS IN TURBULENT PIPE FLOW.

The Cazenovia Creek Model is a physical hydraulic model constructed in the 160-ft x 80-ft (48.8-m x 24.4-m) refrigerated constructed in the 160-ft x 80-ft (48.8-m x 24.4-m) refrigerated research area of the Ice Engineering Facility at the U.S. Army Cold Regions Research and Engineering Laboratory located in Hanover, New Hampshire. The purpose of the model is to reproduce river ice breakup phenomens for optimizing the design of an ice control structure. The optimal design will delay or ultimately prevent the passage of ice flose, eliminating downstream ice jam flooding. The performance of the ice control structure during a simulated breakup is monitored by using an interactive real-time data acquisition system. The data acquisition system is governed by a Hewlett-Packard 9845A deaktop computer and enables a rapid analysis of the work because of the real-time monitoring. This paper discusses the model and its method of data collection.

Zabilansky, L.J., Specialty Conference on Hydraulics and Hydrology in the Small Computer Age, Lake Buena Vista, FL, Aug. 12-17, 1985. Proceedings, Vol.2. Edited by W.R. Waldrop, New York, Ameri-can Society of Civil Engineers, 1985, p.1430-1435, 4 refs.

MODELS, OFFSHORE STRUCTURES, COMPUT-ER APPLICATIONS, FREEZEUP, ICE PRES-SURE, ICE LOADS, ENGINEERING, WATER LEVEL, PILE STRUCTURES.

Marine structures frozen into an ice cover are subjected to vertical forces as the ice sheet responds to changes in the water level. Pile-supported, light duty structures are especially vulnerable to the uplifting forces which can extract the piles from the soil, destroying the structure's integrity. To evaluate the parameters that control the magnitude of the uplifting force a laboratory model study was conducted in a refrigerated test basin.

BOUNDARY INTEGRAL EQUATION SOLU-TION OF MOVING BOUNDARY PHASE CHANGE PROBLEMS.

O'Neill, K., International journal for numerical methods in engineering, 1983, Vol.19, p.1825-1850, 47 refs.

SOIL FREEZING, ANALYSIS (MATHEMATICS), BOUNDARY VALUE PROBLEMS, PHASE TRANSFORMATIONS, CONVECTION, STEFAN PROBLEM, TEMPERATURE GRADIENTS, PIPES (TUBES).

PIPES (TUBES).

Boundary integral equation methods are presented for the solution of some two-dimensional phase change problems. Convection may enter through boundary conditions, but cannot be considered within phase boundaries. A general formulation be complete heat equation, followed by a simpler formulation using the Laplace equation. The latter is pursued and applied in detail. An elementary, noniterative system is constructed, featuring linear interpolation over elements on a polygonal boundary. Nodal values of the temperature gradient normal to a phase change boundary are produced directly in the numerical solution. The system performs well against basic analytical solutions, using these values in the interphase jump condition, with the simplest formulation of the surface normal at boundary vertices. Because the discretized surface changes automatically to fit the scale of the problem, the method appears to offer many of the advantages of moving mesh finite element methods. However, it only requires the manipulation of a surface mesh and solution for surface variables. In some applications, coarse meshes and very large time steps may be used, relative to those which would be required by fixed grid domain methods. Computations are also compared to original lab data, describing two-dimensional soil freezing

with a time-dependent boundary condition. Agrees between simulated and measured histories is good.

TRSTS.

Three sets of helicopter-downwash-produced snow obscuration trials were conducted (two sets on 8 December 1983, one set on 17 January 1984), for a total of 30 individual trials. Both hovering and forward flight patterns were performed. In order to obtain an adequate data base which is relevant to Army scenarios, the planned flight altitudes chosen for the test were for representative flying at low-level or NOE (nap-of-earth) missions and landing. In addition, some test flight trials were directed towards information on "masking" and "unmasking" below and above terrain features or tree tops. Thus the altitudes for the test were primarily restricted to no higher than 50 feet above the surface for forward flights, and 150 feet for hovering. Plights were made perpendicular to the main transmissometer line of sight, or in hovering, vertical take-off and landing modes.

MENT.

Little is known about the response of terrestrial plants to 2,4,6-trinitrotoluene (TNT). To assess its effects, yellow nutsedge (Cyperus esculentus L.) was grown in hydroponic cultures containing TNT concentrations of 0, 10, and 20 mg/L. The deleterious effects of TNT were rapid and occurred at solution concentrations of 5 mg/L and higher. Root growth was most affected, followed by leaves and rhizomes. Root weights were reduced about 95% when grown in the presence of TNT. Plant yields were 54 to 74% lower than the control. The TNT and its metabolites,

4-amino-2,6-dinitrotoluene (4-ADNT), and 2-amino-4,6-dinitrotoluene (2-ADNT) were found throughout the plants. Solutions were continually monitored to ensure that no metabolites were present in solution. Since TNT was the only compound taken up, the metabolites must have formed within the plant. Levels of 4-ADNT exceeded those of 2-ADNT and TNT itself, ranging up to 2200 mg/kg in roots of plants grown in 20 mg/L of TNT. The greatest quantities of all three compounds were found in the rhizomes. Increasing solution TNT levels increased the concentrations and quantities of all three compounds in the plants.

STATION.

Ground truth inputs obtained during an antarctic storm were applied to the Dave vector atmospheric model. The spectropolarimetric properties of upwelling atmospheric radiation are quantitatively related to the number of ice crystals in the optical path. At large scattering angles (smaller angles in the plane of vision), the ice crystal scattering produces strong polarization proportional to the concentration. However, at small scattering angles, the ice crystals cause generally small polarization, permitting the generally large polarization properties of the underlying terrestrial surface to be inferred. Ice crystals, by virtue of their edges, scatter differently than spheres and may have scattering cross sections many orders of magnitude greater than an equivalent area sphere. Polarization appears to be a useful adjunct in synoptic passive atmospheric remote sensing. (Auth.)

ICE CRYSTAL GROWTH, SOLUTIONS, TEM-PERATURE EFFECTS, FREEZING, DENDRITIC ICE, ANALYSIS (MATHEMATICS).

ICE, ANALYSIS (MATHEMATICS).

A finite element solution for ice-crystal growth in subcooled sodium-chioride solution is presented. The freezing process for aqueous solutions requires simultaneous solution of the heat equation in the solid and a complete transport treatment in the liquid region. The moving ice surface in the simulations is continuously tracked via deformable grids. Heat and mass are conserved exactly in the simulations. Specifying the interface temperature based on the constitutional phase diagram is inadequate due to the disparate interfacial growth kinetics for the A-axis and C-axis of the ice crystal. Herein we apply radiation type boundary conditions on the ice interface which maintain temperature close to equilibrium along a fast-growth axis, but allow subcooled conditions to prevail along a slow-growth axis. This preliminary report concentrates on problem formulation and one-dimensional verification of the method against analytic solutions.

MP 2101 MP 2101 PERFORMANCE BASED TIRE SPECIFICA-TION SYSTEM FOR MILITARY WHEELED VEHICLES.

Blaisdell, G.L., U.S. Army Survivable Tire Symposium, Carson City, NV, Nov. 4-8, 1985. Proceedings, 1985, p.277-280, 2 refs. 40-3884
TIRES, MILITARY EQUIPMENT, VEHICLES, DESIGN.

DESIGN.

Most military wheeled vehicles continue to utilize the NDCC tire, despite its extremely low tread life and relatively poor performance. Current tire technology has far surpassed that available when the NDCC tire was designed, yet the Army continues, on all but its newest vehicles, to apply this tire. With such a disparity between the NDCC tire and what is commercially available, and with the potential now to design a tire for numerous specific performance areas, how does the Army determine what tire it should use for a particular vehicle? In answering this question, a working group was formed, and a new tire specification was developed. This system is based not on specific design features in as much as is possible, but on critical areas of tire performance. This system takes into account the vehicle's mission profile and the necessity of certain minimum levels of performance for various conditions.

ERS.

A new technique has been recently introduced that combines time-lapse video techniques with those of thermal imaging. As a result, dynamic thermal events can be recorded in fast or slow motion and played back at expanded or compressed rates compatible with digital enhancement and analysis techniques. The enhancement techniques are used to improve the capability for pattern recognition as well as for the rapid extraction of maximum, minimum and average surface temperatures. The equipment necessary to assemble and operate a typical time-lapse thermal imaging system is deacribed along with some examples of practical and research applications. The capabilities, limitations, and future possibilities are also discussed.

A study to examine orographic effects on atmospheric icing intensity is being conducted on two remote mountaintops in the northeastern United States. The study involves the collection and transmission of meteorological data, including wind speed and direction, precipitation, humidity, temperature, and icing rate. Remote sites are located on Loon Mountain and Cannon Mountain, both situated in the White Mountains of New Hampshire. State-of-the-art instrumentation, consisting of hot cross wire wind sensors, humidity probes, ice detectors and electronic rain gauges, is interfaced with on-site data loggers. The data are transmitted from these remote sites by a specially designed radio telemetry system, consisting of a Tucson Amsteur Packet Radio Terminal Node Controller (TNC) and a Motorola radio link.

CONDUCTOR TWISTING RESISTANCE EF-FECTS ON ICE BUILD-UP AND ICE SHED-

ICING, ICE REMOVAL, CABLES (ROPES), ICE BREAKING, WIND VELOCITY, EXPERIMEN-

TATION.

Two wires of similar diameter (about 1 cm) but with different rwisting resistance or torsional rigidity were tested under otherwise similar environmental icing conditions at the summit of Mt. Washington. It was found that the more rotationally gigid (stiffer) wire affected both the mode of ice buildup and showed some capability of deicing itself in moderate wind conditions. The lesser ice buildup on the stiffer wire is apparently related to the suppression of dynamic twisting oscillations in the wire, oscillations which were apparent in the softer wire. The softer wire showed heavier ice buildup with the wire at the center of a cylindrical accretion. The stiff wire showed less ice buildup on the windward side with the development of an elliptical accretion due to semi-static rotation of the wire. Deicing of the stiffer wire apparently took place by breaking of the ice after it slowly rotated into the wind by several possible mechanisms. The increased drag on the ice as it moved into the wind creates a bending moment which apparently exceeded the failure stress of the ice near where it was attached to the wire. The ice fails and drops off the wire and the cycle then repeats itself.

Rime icing and freezing precipitation are of concern to the radio and television broadcasting industry. This paper discusses the results of a study seeking to document the severity and extent of transmitter tower icing and related problems in the northeastern United States. Information was obtained via mail questionnaire and telephone interviews with eighty-five station owners and engineers concerning 118 different stations. Results show that television and PM broadcasters are seriously impacted, yet AM operators are, in general, only slightly affected by expected New England cing levels. Combined annual costs for icing protection and icing related repairs averaged \$121, \$402, and \$3066 for AM. FM, and TV stations, respectively. None of the AM stations polled employ any icing protection measures, whereas all the TV stations do.

WASTE TREATMENT, WATER TREATMENT, WATER POLLUTION, LAND RECLAMATION, VEGETATION, EXPERIMENTATION, MOD-

ELS.
The efficiency in removing 13 trace organics from wastewater was studied on an outdoor, prototype overland flow land treatment system. More than 94% of each substance was removed at an application rate of 0.4 cm/h (0.12 cu m/h/m of width). The % removals declined as application rates were increased. Removal from solution was described by first-order kinetics. A model based on the two-flim theory was developed using three properties of each substance (the Henry's constant, the octano-water partition coefficient and the molecular weight) and two system parameters (waverage water depth and residence time). The dependence of the removal process on temperature was consistent with the known dependence of Henry's constant and diffusivity on temperature. The model was tested on a second overland flow system.

COMBINED ICING AND WIND LOADS ON A SIMULATED POWER LINE TEST SPAN. Govoni, J.W., et al, International Workshop on Atmospheric Icing of Structures, Trondheim, Norway, June 19-21, 1984. Proceedings, [1984], 7p., 3 refs.

Ackley, S.F. 40-3995

POWER LINE ICING, ICE LOADS, ICE ACCRETION, WIND PRESSURE, UNFROZEN WATER CONTENT, SUPERCOOLED CLOUDS, WIND VELOCITY, TESTS.

During the winter of 1982-83 measurements of combined icing and wind loading, along with in-cloud liquid water content and droplet size, were obtained on a simulated power line test span at the 2000-meter summit of Mt. Washington,

New Hampshire. Icing loads were measured using a triaxial load cell which resolves three perpendicular force components of the wire tension. Wind speeds were obtained from a vaned pitot-static tube located near one end of the test wire. Wind and gravity loading of the test span was obtained for winds up to 30 m/s. The in-line loading, a combination of wind and gravity loads, ranged up to 2500 N for ice accretions of up to 19 cm in diameter. Some indications were found that rougher rime ice accretions had higher drag than glaze accretions.

HYDROLOGIC ASPECTS OF ICE JAMS. Calkins, D.J., Symposium: Cold Regions Hydrology, Fairbanks, Alaska, (1986). Proceedings. Edited by D.L. Kane, Bethesda, MD, American Water Re-sources Association, 1986, p.603-609, 14 refa.

40-407/ ICE JAMS, HYDROLOGY, RIVER ICE, SNOW-MELT, THERMAL ANALYSIS, RIVER FLOW. MELT, THERMAL ANALYSIS, RIVER FLOW.

The hydrologic aspects of ice jams have received very little attention. This paper examines hydrologic information that is important for analyzing ice jam flooding problems, such as flow measurements under the ice cover and winter stage rating curves, frequency analysis of winter flow records, watershed cooling and natural river thermal regimes, ice discharge and snowmelt runoff prediction. The significance of each of these areas is addressed and suggested research opportunities are examined. During the last 30 years, the major emphasis has been placed on understanding the hydraulics and mechanics of ice jams and determining their "flood" levels. However, a parameter that should be known "hood" levels. However, a parameter that should be known with reasonable accuracy is the flow discharge at the ice jam location.

ICEBOUND RIVERS, ICE FORECASTING, RIVER ICE, FREEZEUP, ICE FORMATION, LONG RANGE FORECASTING, ANALYSIS (MATHEMATICS), AIR TEMPERATURE, WATER TEMPERATURE, SAINT LAWRENCE

In this study a method for making long-range forecasts of freeze-up dates in rivers is developed. The method requires the initial water temperature at an upstream station, the long-range air temperature forecast, the predicted mean flow velocity in the river reach, and water temperature response parameters. The water temperature response parameters can be either estimated from the surface heat exchange coefficient and the average flow depth or determined empirically from recorded vie and water temperature date. by from recorded air and water temperature data. The method is applied to the St. Lawrence River between Kingston, Ontario, and Massena, New York, and is shown to be capable of forecasting the freeze-up data.

VARIATION OF ICE STRENGTH WITHIN AND BETWEEN MULTIYEAR PRESSURE RIDGES IN THE BEAUFORT SEA.

Weeks, W.F., Journal of energy resources technology, June 1985, 107(2), p.167-172, 6 refs. For another source see 38-2036 (MP 1680). 39-3284

STRENGTH, PRESSURE RIDGES, PRESSIVE PROPERTIES, POROSITY, TESTS.

PRESSIVE PROPERTIES, POROSITY, TESTS.

A recent series of tests on the uniaxial compressive strength of ice samples taken from multiyear pressure ridges allows the testing of several hypotheses concerning the variation in strength within and between ridges. The data set consists of 218 strength tests performed at two temperatures (-5 and -20 C) and two strain rates (.001 and .0005/s). There was no significant difference between the strength of the ice from the ridge sails and the ice from the ridge keels when tested under identical conditions. As the total porosity of the ice from the keels, the lack of a significant difference is believed to result from the large variations in the structure of the ice which occur randomly throughout the corea. A three-level analysis of variance model was used to study the variations in strength between 10 different ridges, between cores located side by side in a given ridge, and between samples from the same core. In all cases the main factor contributing to the observed variance was the differences within cores. This is not surprising considering the rather extreme local variability in the structure of ice in such ridges. There was no reason at the 5 percent level of significance to doubt the hypothesis that the different cores at the same site and and the different ridges have equal strength means.

COVER STRENGTH, ICE MELTING, HEAT
TRANSFER, SOLAR RADIATION, ALBEDO,
THERMAL REGIME, POROSITY.

THERMAL REGIME, POROSITY.

The deterioration of floating ice covers is analyzed to determine under what conditions the ice cover loses strength due to internal melting. The analysis considers the interaction between sensible heat transfer and long wave radiation loss at the surface, the surface albedo, the short wave radiation penetration and absorption and the unsteady heat conduction within the ice. The thermal analysis then leads to a determination of the porosity of the ice that allows strength analysis to be made using beam-type analyses. The results provide criteris to determine when and how rapidly the ice cover loses strength and under what conditions it will regain the original strength associated with an ice cover of full integrity.

CHANNELS (WATERWAYS), ICE COVER EFFECT, WATER FLOW, BOTTOM TOPOGRAPHY, SANDS, FLOW RATE, BOTTOM ICE, SEDI-TRANSPORT, MENT TESTS. ANALYSIS (MATHEMATICS).

(MATHEMATICS).

The objective of this study was to examine the effects of adding an ice cover to flow in a movable bed channel. A series of five tests at four water discharges were conducted in a 36-m-long recirculating flume facility that is 1.2 m wide and 0.6 m deep. After uniform, equilibrium conditions were established for a flow of water with a free surface, essentially identical runs were repeated with the addition of smooth and rough ice covers. All tests were run at room temperature, approximately 19 C, with simulated ice covers. The sediment was a uniform, 0.45-mm-diameter quartz sand and bed forms were in the ripple and dune regimes. The major variables examined in this paper include bed form height, wavelength, Manning's roughness and sediment discharge.

titutive formulations are used to represent the co Two constitutive formulations are used to represent the constitutive behavior of columnar sea ice under variable path compressive loadings. The first is a single integral representation which has been successfully used to model viscoelastic materials. This representation is a convenient form for describing nonlinear rate dependent properties and is mathematically more tractable than multiple integral representations or nonlinear differential relations. The second constitutive formulation is an elastic-viscoplastic relation which defines the instantaneous strain rate in terms of several microdynamical variables (compressive mobile dialocation density, tensile mobile dialocation density, and specific microcrack surface area).

FRACTURE TOUGHNESS OF MODEL ICE. Dempsey, J.P., et al, IAHR Symposium on Ice, 8th, Iowa City, Aug. 18-22, 1986. Proceedings, Vol.1, 1986, p.365-376, 28 refs. Bentley, D.L., Sodhi, D.S. 40-4558

ICE CRACKS, FRACTURING, ICE STRENGTH, TENSILE PROPERTIES, COMPRESSIVE PROP-ERTIES, STRESSES, STRAINS.

ERTIES, STRESSES, STRAINS.

A wedge-loaded TDCB (tapered double-cantilever-beam) test specimen was used to measure the fracture toughness of model ice. Crack path stability under tensile cracking conditions was ensured by way of the crack-parallel compressive stress provided by the displacement controlled wedge loading. The TDCB specimen size and ice thickness were such that plane strain fracture toughness values were obtained. The influence of crack tip scuity and loading rate were

ICE FRICTION, ICE CRYSTAL STRUCTURE, SURFACE ROUGHNESS, STEEL STRUCTURES, SHEAR STRENGTH, TESTS, AIR TEMPERA-TURE, PLATES, LABORATORY TECHNIQUES. TURE, PLATES, LABORATORY TECHNIQUES. Results of laboratory and field tests on the dynamic friction factor between ice (freahwater, user-doped, and granular or columnar sea ice) and bare or Inerta-coated steel plates of various roughness averages are presented. Laboratory tests were made at three air temperatures, T = -15, -9, and -2 C, with either the ice sample towed over the test plate or a plate sample towed over the ice sheet. All field tests were made at T = -2 C to 0 C. The maximum test velocity was 30 cm/s, and the normal pressure was of the order of 10 kPa. From the test results it is concluded that viscous ahear in the meltwater layer between ice and test plate may dominate when the test plate is very smooth, as proposed by Oksanen in his analytical model, but when the material roughness increases, mechanical shear of the ice crystals dominates.

FRAZIL ICE MEASUREMENTS IN CREEK'S FLUME FACILITY.

Daly, S.F., et al, IAHR Symposium on Ice, 8th, Iowa City, Aug. 18-22, 1986. Proceedings, Vol.1, 1986, p.427-438, 9 refs. Colbeck, S.C.

FRAZIL ICE, PARTICLE SIZE DISTRIBUTION, ICE GROWTH, ICE CRYSTAL NUCLEI, ICE ME-

In a series of recent experiments the dynamic size distribution In a series of recent experiments the dynamic size distribution and concentration of frazil ice crystals were measured in the U.S. Army Cold Regions Research and Engineering Laboratory (CRREL) refrigerated flume facility. These data were found using a crystal imaging system developed at CRREL. The imaging system consists of a circular fiber-optic strobe light, a microscope, and either a high resolution television camera and monitor or a 35 mm camera. The system can observe crystal sizes ranging from 30 micrometers to exacted millimeters. This system was attached to a movable the flume. A series of experiments several minimeters. In a system was attached to a movable carriage mounted on the flume. A series of experiments were performed. In each experiment, the size distribution of the frazii crystals was measured as it developed along the length of the flume. The slope of the flume and the bottom roughness of the flume were varied to provide a range of hydraulic conditions. Supercooling levels of 0.01 C to 0.04 C were achieved in the flume and held constant for several hours.

PRELIMINARY STUDY OF A STRUCTURE TO FORM AN ICE COVER ON RIVER RAPIDS DURING WINTER.

Perham, R.B., IAHR Symposium on Ice, 8th, Iowa City, Aug. 18-22, 1986. Proceedings, Vol.1, 1986, p.439-450, 9 refs.

ICE GROWTH, ICE COVER, FRAZIL ICE, HY-DRAULIC STRUCTURES, ICE DAMS, RIVER ICE, COUNTERMEASURES, FLOODING, TESTS, ICE BOOMS.

TESTS, ICE BOOMS.

The concept of using a trash-rack-like fence across a river to form an overflow weir by accumulating frazil ice was studied. The main purpose of the structure is to create an upstream pool on which a smooth ice cover can form. Laboratory tests in a refrigerated flume provided structural stability guidance and some frazil accumulation experience, with the latter being somewhat inconclusive. Field tests were conducted using a 19-m-long by 1.22-m-high fence boom across two approximately 17-m-wide rivers, one in New Hampshire and one in Vermont.

SUB-ICE CHANNELS AND LONGITUDINAL FRAZIL BARS, ICE-COVERED TANANA RIV-ER, ALASKA.

Lawson, D.E., et al, IAHR Symposium on Ice, 8th, Iowa City, Aug. 18-22, 1986. Proceedings, Vol.1, (1986), p.465-474, 6 refs. Chacho, E.F., Brockett, B.E.

FLOW, SUBGLACIAL DRAINAGE, CHANNELS (WATERWAYS), FRAZIL ICE, RIVER ICE, ICEBOUND RIVERS, ICE BOTTOM SURFACE, SEDIMENT TRANSPORT, VELOCI-UNITED STATES—ALASKA-RIVER.

Repetitive surveys and measurements from 1983 through 1986 of the ice-covered Tanana River near Pairbanks, Alaska, have shown that flow occurs in sub-ice channels that are have shown that flow occurs in sub-ice channels that are separated by longitudinal bars composed of stratified, partly consolidated frazil ice of varying type and distribution. In contrast to hanging dams, these frazil bars extend up- and downstream parallel to flow as well as from the base of the ice cover to the bed, and act as lateral walls for the sub-ice channels. Individual sub-ice channels may branch and require, thus forming a braided pattern beneath the ice cover. Longitudinal frazil bars apparently develop at locations characterized by lower velocities, such as where currents are diverted by irregularities in the bed or in the base of the ice cover.

PRAZIL ICE PEBBLES: FRAZIL ICE AGGREGATES IN THE TANANA RIVER NEAR FAIR-BANKS, ALASKA.

BANES, ALASKA.
Chacho, E.F., et al, IAHR Symposium on Ice, 8th, Iowa City, Aug. 18-22, 1986. Proceedings, Vol.1, 1986, p.475-483, 4 refs.

AGGREGATES, GRAIN SIZE, ABRASION, UNITED STATES—ALASKA—TANANA RIVER. UNITED STATES—ALASKA—TANANA RIVER. A unique form of frazil ice aggregate, the frazil ice pebble, occurs in large quantities in the Tanana River near Pairbanka, Alaska. Frazil pebbles consist of a mixture of individual particles, including other aggregates, which are bound together to form a consolidated, compact mass that is similar in appearance to water-worn stream pebbles. Frazil pebbles have been found incorporated into the ice cover, in transport beneath the ice cover and in frazil deposits. They range in length from less than 5 mm to greater than 150 mm. Internally, grains composing the frazil pebbles do not possess a preferred C-axis orientation, but appear to show an alignment related to grain size and shape.

MP 2131 POTENTIAL SOLUTION TO ICE JAM FLOOD-ING: SALMON RIVER, IDAHO.

Barickson, J., et al, IAHR Symposium on Ice, 8th, Iowa City, Aug. 18-22, 1986. Proceedings, Vol.2, 1986, p.15-25, 10 refs. Zufelt, J.E.

TROL, DESIGN, ICE BOOMS, UNITED STATES
—IDAHO—SALMON RIVER.

—IDAHO—SALMON RIVER.

The uppermost 140 miles of the Salmon River generates great quantities of frazil ice throughout Idaho's cold winters. A freeze-up ice jam forms at a slackwater region 27 miles downstream of the city of Salmon, Idaho every winter, and often progresses upstream to the city. As the ice jam moves through Salmon, the river level can rise 6 to 8 feet and cause extensive flooding. Flooding has occurred at least 32 times since 1900, and the 1982 flood caused \$1,000,000 in damages.

MP 2132 DESIGN AND MODEL TESTING OF A RIVER

Tatinclaux, J.C., IAHR Symposium on Ice, 8th, Iowa City, Aug. 18-22, 1986. Proceedings, Vol.2, City, Aug. 18-22, 198 (1986), p.137-150, 16 refs. 40-4591

40-4591
ICE NAVIGATION, RIVER ICE, ICE CONDITIONS, ICE BREAKING, DESIGN, DAMS, LOCKS (WATERWAYS), MODELS, TESTS.
One of the tests in the Corps of Engineers River Ice Management (RIM) program is to develop an ice prow capable of creating nearly ice-free channels in the vicinity of locks and dams on the Illinois and Ohio Rivers. Based on a literature survey the selected concept was that of a barge type attachment to be mounted ahead of a towboat. The prow is equipped with ice knives, and has a gently sloping bottom equipped with deflector vanes. The paper presents the results of model resistance tests which served to select the vane configuration and number of ice knives. A prototype of the prow is under final design for construction; field testing and demonstration are acheduled for winter 1986-87.

BUBBLERS AND PUMPS FOR MELTING ICE. Ashton, G.D., IAHR Symposium on Ice, 8th, Iowa City, Aug. 18-22, 1986. Proceedings, Vol.2, 1986, p.223-234, 8 refs.

ICE MELTING, BUBBLING, WATER TEMPERATURE, PUMPS, WATER FLOW, HYDRAULIC JETS, ANALYSIS (MATHEMATICS).

JEIS, ANALYSIS (MATHEMATICS).

Air bubbling systems and submerged pumps have both been used to induce a jet-like flow of warm water against the underside of ice sheets resulting in ice melting. The mechanics of sir bubbling systems for this purpose has been analyzed previously and analytical methods are available to evaluate their effectiveness. A similar analysis of the melting caused by pump systems is presented. A comparison of the effectiveness of bubblers and pumps is made in terms of power. Finally the advantages and disadvantages of the two kinds of systems are contrasted.

FLEXURAL AND BUCELING FAILURE OF FLOATING ICE SHEETS AGAINST STRUC-

Sodhi, D.S., IAHR Symposium on Ice, 8th, Iowa City, Aug. 18-22, 1986. Proceedings, Vol.2, [1986], p.339-359, Refs. p.356-359. 40-4604

COVER THICKNESS, ICE ADHESION.
This is a review of work on bending and buckling failure of floating ice sheets, along with the forces generated during ice structure interaction.

The focus is on the work published after 1980. Estimation of ice forces as a result of bending and buckling failure of an ice sheet can be made with a fair degree of confidence when the ice structure interaction of multimodal failure of floating ice sheets needs further study.
